Jim,

Yup, that's right. I just find the other way easier to remember. I wonder if there is a 4V150 out there that's vapor cooled with a glass seal ....

I might also ask what are you doing on my tax money (hey, you have a .GOV address) putting out a message like this?

I just put in Verizon DSL and it played the first time and worked just fine, thank you. Beats the dial up to AOL any day.

I don't put the laurels at the feet of Verizon folks to put this in place - it was the dedicated electrical engineers (not software weenies) who figured out how to put 500 kbps over the twisted pair that are the heros.

4. Re: How determine SSB PEP?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-01 03:10:44 UTC
From: Greg Knapp <gknapp@freshrain.org>
Message-ID: <t4vtbtes3e02b1@corp.supernews.com>
Source record: 55701

I want to thank everyone for sharing their wisdom directly with me via E-mail or here on the newsgroup. Apparently it is quite difficult to measure SSB PEP in real life QRP QSOs (as opposed to 2-tone tests) without an actual PEP reading meter.

Especially thanks to Steve, KZ1X/4, who sent me the W1HUE PEP circuit mod to the WM-1 / WM-2 which will allow direct reading of PEP on my soon-to-be-built QRP wattmeter. It should do the trick.

Again, thanks to all who replied, I really appreciate it, and 73...

Greg, N6GK

5. FS: OHR 100A CW QRP Transceiver

Hi All,
I have a reently built OHR 100A CW transceiver for sale. The rig was built and tested by me and fully aligned. It works great and puts out about 7 watts max power. It is setup for the general portion of 40M.

The rig sells for $129.00 from OHR. I will sell this one for $100.00 shipped/insured.

Pictures available on request.

Regards,
Jeff W8CQ

In addition, some rigs (e.g. the IC-706) are notorious for first
generating nearly the full power before the ALC limits the power when
the transmitter is operated at lowest power settings (e.g. for driving
a transmitter). With such transmitters using a peak reading meter with
hold, will show that first large initial peak.

The compound is definitely toxic, but it doesn't contain mercury. It's an organic compound based on carbon, hydrogen, nitrogen and sulfur.

Are you sure about that? "Thio" refers to sulfur, and urea is a simple organic compound containing nitrogen, carbon, and hydrogen.

Synonyms: isothiourea, sulfourea, 2-thiourea, USAF EK-497, pseudothiourea, thiocarbamide
Molecular formula: C H4 N2 S
CAS No: 62-56-6
EINECS No: 200-543-5

No mercury there. Perhaps you were thinking of thimerosal?

An old-fashioned cleaner for silver is plain old household ammonia solution
available in any grocery or convenience store for less than a dollar. Just
brush it on with a small brush, like a small paintbrush, scrub it a little
and viola, you have a clean shiny silver surface. To clean the amonia off,
one can use plain water or rubbing alcohol. No need for polishes or other
stuff (containing only God knows what) to clean the tarnish off silver.

http://www.jensen-transformers.com/as/as020.pdf

Of course for commnications use, you can (should?) use a lower-quality (cheaper) transformer. You don't need the wide frequency response and ultra-low distortion of the Jensen products Additional schematics at:

Any of the methods (xDSL telco, cable, even sattelite) are dependent on the business decisions of the carriers. How much bandwidth will they provide vs. growing number of customers per hub/transponder?

In many cases the customer service response may be more significant than the data rate of DSL vs. cable. YMMV depending on who your local vendor(s) are and how their local management runs the operation.

RC in OR
still using 26.4K dialup (no DSL or cable in my neighborhood)

18. 400Mhz RF Signal upconverter circuit ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-01 19:11:20 UTC
From: "Lindsay C. Blanton" <lblant1@airmail.net>
Message-ID: <c4l15tobfpt1fd83v5g9t4n29v7na2q68u@4ax.com>
Source record: 55715
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.design

Hello everyone!

I'm attempting to find some information on how to build an RF up converter circuit for the 400 Mhz band.

My requirements are to be able to up convert signals in the 450-465 Mhz band to exactly 40 Mhz higher (to 490-505 Mhz).

Ex.

460.025 Mhz --> [Up converter] ---> 490.025 Mhz

My problem is, I've got a receiver that only receives in the 480-512 Mhz band, but I need to allow this receiver to monitor signals in the 450-465 Mhz band. There are no transmission requirements, only the need to attach an antenna to the input of this up converter, and then attach the output of the up converter to the antenna input of the receiver.

I'd prefer to build this circuit myself, but if there are commercial products available that will accomplish this I'll consider those too...

I'm hoping someone can help!

Warmest regards, and Happy new Year!

>> Jim Pennino

I've used the EASYTRAX package for producing my artwork (Freeware,
courtsey of the Protel corporation.) While EASYTRAX only produces
postive artwork, there is an add-on program, called CONVERT, which
will convert the positive artwork to negative artwork. This program
is available on the RCS Radio web-page:

http://www.cia.com.au/rcsradio/

(Bob was talking about selling the company, but I haven't heard
anything recently. Bob, if you're reading this, I hope you're doing
well after the accident.).

I've made several PC boards using the thermal transfer technique
with a laser printer, and, while it works, I'm not satisfied with the
repeatability. Sometimes, the boards turn out fine, other times,
the toner/resist fails to adequately stick to the copper. I'm not
sure if it has to do with the type of paper (regular copier paper,
heavy-weight paper, glossy/photo paper, etc.), with the toner
used in the laser printer, with the cleaning/preparation of the

board, with the temperature of the thermal transfer process,
or if it has to do with something else.

I'm planning on giving the photographic technique a try later
this year (Too many things to do, not enough time.). I'm aware
of both a negative and a positive photoresist, although the
existance of the CONVERT program makes this pretty much
a moot point.

I've thought about trying the direct plot on the board approach,
but I've not had much luck finding a flat-bed plotter (HP used to
make one decades ago, although I'm not sure how easy it
would be to interface it to a modern system. I think there's another
manufacturer who makes a reasonably afforable (used) flat-bed
plotter, but, I can't recall the name.).

Lindsay,

Depending on the result you are trying for the converter isn't all
that hard or may be nearly impossible.

Here's a few quick easy thing to try:

1) cheap, dirty and probably not useful:

Take a Mini Circuits mixer and hook the antenna to the RF port.

Hook a signal generator tuned to 40 MHz to the LO port.

Pull the output off the if port.

Should give you about 6 db of loss and lots and lots and lots of
spurs.

2) not quite so cheap, still dirty, may be useful:

Same hookup as 1 above, only set the signal generator to 465 + 490 =
955 MHz.

Same loss, still a lot of spurs, but not as bad as in 1 above.

3) Spend more money:

Put an RF bandpass filter in front of the mixer. Try hamfests or eBay
for one since they can be fairly expensive ($400+) purchased new.
Cuts down on the spurs.

4) Spend still more money:

Put an SAW if in between a pair of mixers ....

At this point you are building a receiver from scratch ....

All said, if the simple lash up's are not adequate a new receiver may
be cheaper than a converter. Obviously if the simple setups work then
you can replace the signal generator with a fixed frequency
oscillator. If they don't work you are only out the price of the
mixer.

Hope this helps ....

Bob

That's certainly true. I always chuckle when I see someone in the lab search for an antenna adapter, and grab a nice shiny one rather than an ugly tarnished one.

26. 400 Mhz RF Up-converter circuit?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-01 21:23:59 UTC
From: "Lindsay C. Blanton" <lindsay@lcblanton.com>
Message-ID: <zB646.41$7T1.72681@nnrp3.sbc.net>
Source record: 55724

Hello everyone!

I'm attempting to find some information on how to build an RF up converter circuit for the 400 Mhz band.

My requirements are to be able to up convert signals in the 450-465 Mhz band to exactly 40 Mhz higher (to 490-505 Mhz).

Ex.

460.025 Mhz --> [Up converter] ---> 490.025 Mhz

My problem is, I've got a receiver that only receives in the 480-512 Mhz band, but I need to allow this receiver to monitor signals in the 450-465 Mhz band. There are no transmission requirements, only the need to attach an antenna to the input of this up converter, and then attach the output of the up converter to the antenna input of the receiver.

I'd prefer to build this circuit myself, but if there are commercial products available that will accomplish this I'll consider those too...

I'm hoping someone can help!

Warmest regards, and Happy new Year!

Not knowing the type of receiver you have, it may be much easier to move it
to the desired freq range by changing its LO.

Give me a break! Even Einstein would know that a fixed 40MHz oscillator and mixer combination beats a * tunable * LO oscillator. He can buy a little 3dBm mixer for about $2, a 40MHz osc for $5, and he is there. The mixer should be double-balanced and he will not need a filter- closest product down 20dB at this frequency. He may take a 6dB hit in conversion loss so he has about 30% reduction in reception range for the same S/N; or he can listen to same range with a little less S/N. Or he can spring for a MAR and be about the same.

Hi,

Some years ago I witnessed a demonstration of an on-frequency repeater made by Plessey in the UK. One of its main uses was to provide radio shadow fill-in on the battlefield and as such was meant to be left unattended. The antennas were a couple of monopoles spaced a few metres apart and except for a low power provision (10mW or so, which is common on military gear) there was no obvious method of stopping RF blocking. I had the manual in my hand at one time but regret that I didn't get round to reading it before it was whisked away. Does anyone remember this or shed a little light on the subject? As I recall it didn't use a small offset and narrow filters but I could be wrong. I suspect that the receiver was somewhat deaf though.

Silver oxide isn't a better conductor than silver. But tarnish is primarily silver sulfide, which is about 100,000 times less conductive than silver. The amount of loss it would introduce depends on the thickness and frequency.

Where did you read that silver oxide is more conductive than silver? The writer would be an author to avoid.

Who said the LO was tunable..we don't know. If I was looking at this project
and I wanted to only tune the bandwidth listed and had no need for the old
bandwidth, I would look hard at what I suggested.

Amen!

I recommended a visit to the Cool Amp site and request a sample of their powder. Not only clean the silver, but add additional plating.

I automatically do a double take when someone tells me a corroded surface is more conductive than one not. Some folks will believe ANYTHING.

I believe Einstein would have been more interested in the
frequency change of the fixed oscillator in an accelerating frame
relative to an observer in a "fixed" frame.

Surely not! All the vapor cooled tubes that I'm aware of are 100,000
Watts and above. ;-)

I got a quote a few months ago for some 4CV250,000 tubes as possible
replacements in case I blow up one of the 175kW tubes in my current
assignment, for which we have no spares. The price was ~$15k @ once
you added in the new collets, etc. OUCH!

I think this means I need to be careful with the ones I've got.

> system
> for a big tetrode. Also any real drawbacks to water cooling.

Where I work we have used large water cooled triodes for induction heating uses in a power oscillator circuit from power levels of 30 KW to 150 KW. We found there are several issues with water cooling a large power tube. These tubes were "designed" for liquid cooling, and not modified air cooled versions.

1. The water quality. The water has to be very clean and non-conductive. You can use deionzied or distilled water. You should check the conductivity of the water at regular intervals.

2. You may need to use "targets" at the anode of the tube. The target will slowly dissolve in to the cooling water instead of the tube's anode, or the water cooling jacket the tube sits in. The targets should be installed at the anode of the tube, and in line where the water enters, and exits the cooling jacket.

3. You MUST use non-conductive hose for all water connections. You would be very surprised by how many hose materials are conductive or break down at high anode voltages. The best thing to do is test a sample at the volts per foot you will be using.

4. Watch your hose length! You need enough length of hose to keep electrolysis to a minimum so your targets don't "disappear" after a few weeks or months of operation. Don't forget to check the targets on a regular schedule either. We have used about 20 to 30 feet of nylon reinforced Tygon hose, 1-1/2 inch size, at anode voltages up to around 15 to 18 KV. The hose has to be suspended in air away from anything conductive connected to ground along its length, until you get to the end fittings which must be grounded. If you don't, the high voltage/RF will "burn through" the hose from the water inside to the ground point! This is most important near the tube's anode of course. In place of using hose I have seen PVC pipe used too with the same notes applying as for the hose.

5. You will need some control logic to be sure you have water flow BEFORE you turn on the tube filaments! Some of the tubes I have seen take 14 volts at 250 to 350 amps. That heat has to go somewhere!

6. You will also need logic to let the tube cool down for some minutes after the anode voltage is removed BEFORE the cooling flow is shut off.

7. Finally you will need logic to dump the anode supply voltage in case of cooling flow failure, or coolant over temperature condition. Also an Emergency-Stop switch to shut off the coolant flow, pump, and anode supply voltage in case of a coolant leak is also recommended!

The above is the basic things you need to consider for a liquid cooled tube application. There maybe a few minor points I forgot to mention however.

You could look at http://www.tentec.com. They also have a kit for 6
meters. They might sell you a schematic and construction manual.

I will like to get for a parametric Eq and i will like to know if any of
you knows from the EQX-2 by LA Audio?
http://www.laaudio.co.uk/PRODPAG/eqx2.htm
or if you have another one than you know let me know about your opinion.
It will be to use with my FT-1KMP.
the audio device project will be:
Eq like EQX-2 (LA Audio).
Mix as MX602 (Behringer).
Mic as NT-1(Rhode).

40. Cleaning tarnish from silver

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-02 05:48:24 UTC
From: Barry Ornitz <ornitz@dpnet.net>
Message-ID: <nVd46.9162$dm4.802308@news-east.usenetserver.com>
Source record: 55737

Boy, some of the answers on cleaning tarnish from silver have been quite humorous but completely wrong. To correct a few things: all "thio" compounds are sulfur containing (not mercury), silver oxide is not more conductive than metallic silver but it is more conductive than silver sulfide (black tarnish),

The simplest process for cleaning silver of tarnish is described below. It is likely what Henry Kolesnik was trying to remember. It does not remove any silver, unlike polishes. It reduces the silver sulfide to metallic silver. The only problem is that the silver or silver plated part must be immersed in an aqueous solution.

To begin, find an aluminum pan that is deep enough to hold the part. It is best not to steal the wife's Mirro cookware. A disposable pan like grocery stores sell for holiday baking is excellent. Fill the pan with water and add a little table salt (sodium chloride) or baking soda (sodium bicarbonate). No more than a half teaspoon is necessary. Now dunk the silver part in the pan and allow it to rest on the aluminum. It must make electrical contact to the aluminum. To speed things up, heat the water. You will quickly find the black discoloration on the silver dissolves and the aluminum pan will darken.
Rinse the part well after removing it from the solution. The finished silver part may not come out very shiny (but it will be bright). This is because the process only removes the sulfur. If you mechanically polish the silver, you WILL remove some silver.

What is happening is an electrolytic oxidation-reduction chemical reaction. The silver sulfide is reduced to metallic silver with the sulfur ions going into solution. They react with the aluminum making it black. The electrical contact is needed for the electrolytic reaction to take place. The aluminum reaction is the oxidation.

If you did accidentally use the wife's fancy pot and you are too lazy to scrub it with a scouring pad, you can cook some tomatoes in the pot. Their acidity will dissolve the aluminum sulfides. The added sulfur in the tomatoes is generally not harmful but it can give some awful flatulence!

The fancy product sold on television that has a liquid and a "magic" metal plate to put in the bottom of a bowl is essentially just this - at a far higher price! That metal is just aluminum.

Cool-Amp powder is sold in large electrical supply stores. You add a little water to it to make a thick paste and rub it on copper to produce a thin silver coating. It works quite well. The main use is to coat electrical buss bars and breaker contacts with a thin silver plating to reduce contact resistance. The stuff is quite expensive and they only sell

it in one pound jars. A jar will last you and your friends a lifetime however.

By the way, while I am the "resident chemist" on the Old Tube Radios mailing list (Boatanchors), I am really a chemical/electrical engineer.

It is usually better to have a tunable receiver moved to the desired band than having a fixed converted followed by the original tunable receiver when looking at the number of potential spurs.

However, if the original receiver has a good front end selectivity, then in addition of moving the LO, the front end filters would have to be retuned for the new band, which can be a hard task, if complex filtering are used.

>Or he can spring for a MAR and be about the same.

Have you ever connected an antenna directly to any of those low noise MAR amplifiers in the vicinity of strong transmitters ? You need quite a lot of selectivity in front of the MAR amplifier to protect it from overload or you have to use some of the high IP3 versions in the MAR series, but the noise figure is not much better than a SBL series diode ring mixer.

>1) cheap, dirty and probably not useful:

>Take a Mini Circuits mixer and hook the antenna to the RF port.

>Hook a signal generator tuned to 40 MHz to the LO port.

And you have the image frequency band at 530 .. 545 MHz. This is in the UHF television broadcast band so if there are _any_ TV broadcasts detectable in that range at your location, then these will produce image frequencies with the same intensity as the desired signals, unless some heavy bandpass filtering is used in front of the mixer.

>Pull the output off the if port.

>Should give you about 6 db of loss and lots and lots and lots of
>spurs.

However, if you are lucky, no TV broadcasts are detectable in that frequency range in your area, so even with no front end selectivity, this system will be quite usable, although the effective noise figure will degraded by a further 3 dB due to the band noise in the image frequency range, so the total noise figure would be more than 9 dB.

>2) not quite so cheap, still dirty, may be useful:

>Same hookup as 1 above, only set the signal generator to 465 + 490 =
>955 MHz.

>Same loss, still a lot of spurs, but not as bad as in 1 above.

Please note that

955 MHz - 450 MHz = 505 MHz (frequency difference 55 MHz)
955 MHz - 465 MHz = 490 MHz (frequency difference 25 MHz)

Thus the receiver would tune in _opposite_ direction, the frequency difference would not be 40 MHz as required, the sidebands would be flipped and so on.

>3) Spend more money:

>Put an RF bandpass filter in front of the mixer. Try hamfests or eBay
>for one since they can be fairly expensive ($400+) purchased new.
>Cuts down on the spurs.

Toko made quite a few helical filters in that frequency range for
maybe $5 .. $10, but the insertion loss was about 2 .. 6 dB.

Your point about 'frequency difference' is misleading. With the 'osc.
high' configuration, the new tuning range is 490 to 505 MHz, as
required. Reversing the tuning direction is probably not a big
disadvantage. Inverting the sidebands may or may not be a problem
depending on what signals are to be received.

Joe

If the gain exceeds the isolation for a continuous real-time repeater configuration, there are immediate stability issues. Ways around this are either exoensive or use time-slicing. The current TETRA equipment achieves this function with four timeslots, permitting a "normal" TETRA mobile to act as a repeater or "range_extender" to a hand-held in a normally shadowed area.

The product that the post was referring to was described in Wireless World quite a few years ago.
Long before Tetra, although they may have been the digital modes that were used around that time, such
as frequency hopping and etc. It is also conceivable that standard FM may have been used synchronies
regeneration and isolators may have made it possible. Although as you rightly point out tetra and
similar schemes tend make those ideas redundant.

Barry - My searching of technical papers disagrees with you on one point - "Sulfur-containing atmospheres will produce silver sulfide that increases contact resistance. "

What is the conductivity of silver sulfide?

Ok, I'm thinking I'd like to try option #1 -- purchasing a mixer and feed 40 Mhz LO into the Mixer.

I think I can work around the TV Image issue -- we really don't have TV stations in this range in my area.... if I did, I could adjust what I feed LO to get around that. The signals that I want to receive are fairly strong, so 9Db of loss should be acceptable....I hope ;-)

The radio in question is an Motorola ASTRO spectra... and I don't want to muck around with tuning this radio etc.

Now, I've got a few questions about this....

1. What is a good suggestion for a good mixer. I've heard Mini-Circuits makes a good mixer -- but which one do I choose? I see lots of different options on their web site.

2. How do I build a signal generator to feed 40 Mhz into the LO port? Are there are sample circuits around?

If anything, this will be a fun project to tackle....

Please respond via email as well as the list -- my news server is spotty at best.

Warmest regards to all,

Lindsay Blanton

> filtering are used.

I disagree because the performance of the existing receiver is being used to advantage. The front end is presented with the same RF mix as usual- he is only shifting one band into another. The selectivity will remain the same. As you say, the conversion will put other channels and mixing products into the same band. There may be a problem with image reception but 400/40=10 is an easily achievable Q at 400MHz. He will also have an interchannel modulation of in-band that will down by 2*(IP3-Pin) of the mixer, and this is usually not a problem with reasonable Pin expected off the air- but should be considered. So he should use a preselector (homemade coil+cap) if there's anything in that 360-400MHz band nearby.

> diode ring mixer.
>
> Paul OH3LWR

This is a good point- even with high dynamic range MAR, the interference will desensitize the mixer and effectively destroy the S/N of the desired channel. You would have the same problem without the MAR since relative signal level is what's important. He should look into a simple preselector (fixed-band) input filter. As you probably know, the NF of the mixer is effectively the conversion

loss- so the MAR doesn't buy him much in the way of NF improvement. The mixer VSWR should be workable over this limited range.

52. Wesite on ATV and other info ....

53. Mixer Diodes - Homebrew Spectrum Analyzer

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-02 19:33:04 UTC
From: Bob Camp <bob@cq.nu>
Message-ID: <Q1q46.83176$nM5.13120844@news02.optonline.net>
Source record: 55650

My homebrew spectrum analyzer project took an odd twist about a week ago. My employer tossed out a HP 8590A and I happened to fish it out of the trash ....

It seems to have all the basic parts one would want to use to build a spectrum analyzer out of save for a pair of good diodes in the mixer. The HP service manual lists an in-house part number (5062-0785) for them that is on the "no longer available" list (or so I am told ....).

So the first question - given that this is ham radio and not NASA and that the objective is a spectrum analyzer in the basement and not in a cal lab ..... what's a good pair of mixer diodes to try ?

The second question - any body out there have any experience with these gizmos ? If so I've got a couple of questions ....

Thanks !

On a similar subject, how does the 'Channel Radio' on 117.7MHz work (as you approach the Channel Tunnel terminal on the M20 motorway)? They use cross-polarised (45/45 degree) log periodics, on 30' poles about 20 feet apart, pointing away from each other.

There is no sign of a glitch when you pass a repeater site (spaced at appx 1 mile intervals). Do they rely purely on having good isolation between the two antennas, or do they also use a small, alternate frequency offset (say =/-25kHz wrt the nominal frequency) to increase the isolation? The 'ultrasonic-ness' of the 50khz beat (as you pass from zone to zone) plus the capture-effect of the FM receiver should ensure glitchless reception.

Also, how do they provide a similar continuous coverage (on 117.6MHz) on the motorway between Calais and Paris? You keep passing roadside antennas (looks like some form of co-linear), but there's no obvious sign of repeaters. Do they simply use modulated transmitters at each site (with small, alternate frequency offsets, if necessary)?

Ian.

Sounds like you hit the jackpot. What connections are made to the
8590's mixer module? Any of the Mini-Circuits 2 GHz DBMs ought to work,
at least as a first attempt. Use the DBM's IF port as your RF input,
and vice versa, for RF coverage down to near DC. You'll lose a couple
dB worth of amplitude calibration accuracy but it'll still be
light-years better than any of the homebrew SA designs out there.

There will probably be a DC bias on the mixer for amplitude-levelling
purposes -- perhaps fed in through a bias tee, if not through a pin on
the mixer assembly. Leave this disconnected if you use a DBM.

Otherwise, given the low (1.5 GHz) frequency ceiling of the 8590, I'd
suggest just trying any old random Schottky diodes you can find.
Nothing to lose, right?

You hit most of the important items.

We used 3/4 inch tubing wound on a phenolic form on systems as high as 175 KW.

At the highest of legal amateur power levels the flow and pressure would not have to be very high. I'd still want at least 8 or more feet of tubing between the plate and ground with only 4 or 5 KV.

As for water resistivity I built a probe with 1 CM square plates separated by 1 CM hooked to a Simpson multimeter to get a rough approximation of ohms per CC.

I don't remember our target resistively though. Seems like it was close to 100K/CC, but it may have been less.

I want to thank Barry for yet another informed and comprehensive post. It's now in my reference archive along with quite a few others of his.

I'd like to make a point about conductivity. If you coat a wire with a perfect conductor, you won't increase its loss -- it just thickens the wire. If you coat it with a perfect insulator (think of air), that won't increase the loss either. These are opposite ends of the conductivity (or resistivity if you prefer) range. Loss occurs when a coating is neither a perfect conductor nor a perfect insulator, and it's maximum with some value in between. At what value? Well, it depends on the frequency, conductivities of the coating and wire, and the coating thickness. I'd like to get a better feel for some typical cases, and have the equations for coated wires, but haven't had the time to work them into a program. (They require complex Kelvin functions, which I haven't yet located a calculation algorithm for. I haven't had time to search.) But in the meantime, don't just assume that higher resistivity in a coating is necessarily worse (or better). It depends.

Roy - I agree with you up to a point. In RF we have to deal with skin effect at the higher frequencies. That being said, a layer of silver bonded to a copper conductor will improve the conduction of the RF signal. The same philosophy is used in the "Copperweld" conductors, albeit a much less expensive solution. They coat steel cores with bonded copper. It provides the strength, reduces the stretch factor, and addresses the skin effect.

The only reason that gold is used in electronics is that it does not tarnish, therefore reducing the conductivity. Silver would actually be more preferable except that it indeed tarnishes - silver sulfide. Silver has better conductivity than gold. Not everone understands this.

I was talking about the loss of wires, not contacts. The requirements are quite different for the two applications. An enameled contact isn't much good, but "enamel" insulation has no significant effect on wire loss. Silver is widely used for contacts, but only ones that carry considerable voltage and current. The normal arcing that occurs (along with contact wiping action) cleans off surface oxides and other contamination each time the switch closes. Quality switches for "dry circuits" -- ones carrying little voltage or current -- are almost always gold plated. Without the arcing to clean the contacts, even a small amount of surface contamination is intolerable. You can buy switches for either purpose which have thin gold over heavy silver. But once you use it to switch a high power circuit, the gold is gone and you can't use it for dry circuits afterward.

Copperweld and similar wire works because the plating is thick enough that no significant amount of current penetrates to the underlying steel. Skin depth is very small in good conductors like copper. But as the conductivity of a plating decreases, the skin depth increases. When the skin depth gets to be on the order of the plating thickness, the problem gets more complex.

The conductivity of pure metals is usually beside the point. Alloys commonly used for plating often have conductivities very different from pure metals. For example, most silver plating alloys are much less conductive than copper. Not may people understand this, either.

Some added comments while we are on the subject of silver, silver plating, and wire coatings....

First, thanks Roy. I have learned much from your posts over the years too.

Gold is used in contacts not only because it is tarnish resistant, but also because it is so soft and maleable. This allows two slightly irregular surfaces to make better contact. On printed circuit board edge connectors, it is common to electroplate nickel over the copper before applying a thin "flash" of gold. The term "flash" in this case is electroplater's jargon for a very thin coating, often obtained from a cyanide bath. "Strike" is similar plater's jargon and sometimes the two are used interchangeably, but usually a "strike" layer is a thin layer used over a base metal to provide better adhesion for a thicker layer to be applied in a second bath.

Silver can be electroplated in a quite pure form. But the crystalline structure of the plated layer may be quite different than in a cast metal. This leads to the differences in conductivity often found. Changing the electroplating conditions even slightly can cause extreme changes in the crystalline structure of a coating. Sometimes it is possible to do a quick reflow by heating the object quickly above silver's melting point and quenching it afterward.

The silver coating obtained from Cool-Amp powder is hardly pure and extremely thin. It helps a little for corrosion protection of bare copper, but do not rely on it to replace a thick silver plate. In fact, I doubt if most hams could ever measure a Q improvement in a typical coil that was thickly silver plated over a bright, shiny copper one of the same dimensions. Coating the bare copper conductor with a low-loss dielectric coating (like Krylon acrylic) will keep the copper surface shiny and conductive. But, being an insulator, it is no good for moving or sliding contacts.

In the chemical and paper industries, gold plated switch contacts are the norm. In fact, conformal coatings on circuit boards used in control systems is common. There is nothing so disheartening as to open an electronic cabinet and see your circuit boards corroding away! Hermetically sealed relays and reed switches are common in these

industries both for corrosion and to not be an ignition source in explosive atmospheres.

Finally for those that read the excellent article on skin depth and conductors in the last QEX, it should be remembered that many stainless steels are slightly ferromagnetic. Even the 300 series can be changed into a magnetic form by machining and polishing. Once the conductor becomes magnetic, its skin depth decreases increasing RF losses. So not only do the stainless steels have a lower conductivity than copper, their magnetic properties can provide even higher RF losses.

re: Swan 1011 and Siltronix 1011 Tranceiver web page.

Hello there!

Another shameless plug to tell people about the updated Siltronix web page at http://sonic.ucdavis.edu/siltronix

Hot off the press! We have added pictures of the prototype Swan - Siltronix 1011 tranceiver. Even better yet, we've added more text information and an Owner/Service Manual down load for free.

Life doesn't get any better... well maybe, but not yours. Have a look and Email us what you think.

thanks and 73's

cheers

<snip>

Well, don't come to Heyworth, Illinois. IF I ever had children (no plans!) and IF they had children, my grandchildren would be surfing the net with 56K dialup. IF we ever get anything faster here, most likely I'll be too old or dead by that time! And - we're only eleven miles from Bloomington/Normal, one of the fastest-growing urban areas in the Midwest.

It's a good thing electrification of this country wasn't left to "market forces" and "business decisions". Here in central Illinois, most likely we'd still be using oil lamps (maybe generators would've made it here by now).

My partner regularly chats with a friend in Tanzania. In that country, *any* home that wants DSL can get it easily. Funny how "the most technologically advanced country" can't say the same. But then, other countries don't have Verizon, SBC, Pac Bell, and the rest holding a death grip on their telecommunications. This is the country that put a man on the moon way back in 1969 and that invented the Internet (and no, I don't mean Al Gore. Let's retire that one, since it never happened and he *didn't* say it). And we can't roll out realistic-speed Net access to anywhere in the country? Pure USDA-grade BS.

Above all the noise, there's one thing that's clear. The Internet will *never* reach its potential as long as dialup is still so prevalent. How can e-commerce prosper when it takes so long to load a page? Sure, part of that has to do with web authors that put too much crap in their HTML, but on the other hand their designs shouldn't be needlessly restricted by dialup

deficiencies and ancient legacy technology.

I'm not interested in "business decisions", "return on investment", or any of that other get-the-telcos-off-the-hook nonsense. I am interested in being able to access the Internet at faster speeds than 1960s-era dialup. I don't care whose wire it is - the copper's been paid for many times over. And no, satellite "offerings" from Dish or DirecTV aren't an option, either, unless you want to pay for new equipment and installation, and high monthly prices.

Thank the Gods the telcos never got their hands on Amateur Radio. We'd still be in the spark-gap era, CW for the military, and voice for the business interests!

im going to build up a tuner here soon and was wondering
whats really the good and bad as far as
useing the ..T MATCH ...L...OR ....PI DESIGN

im leaning more to the good old PI . I HAVE TWO GOOD 500PF
VAC VAR CAPS and and nice heavy roller inducter

i would want to tune a 1250 ft h loop feed with 450 ladder line
160 thur 10 . maybe with a 4to1 balun and plus tune a coax feed dipole
cut for 75 meters and one for 40 . just as a touch up

the antenna switching isnt a problem.

design and balun placement are..4to1 before or after network?
ive seen it both ways

Joe,

Since you know what antennas you want to match I would start there. If the antennas are up already I'd measure them. If they are still in the planning stage I'd try one of the antenna analysis programs. Either way you can get the feed point impedances for what you are trying to match.

Once you have that and your feed line length(s) you will know what the tuner needs to do in your application. You may well find that some odd configuration of parts is needed to match what you have on the bands you want to work. It may save you a switch or some re-wiring of the tuner.

Do you know what the size of the coil you have is ? You can probably estimate it pretty accurately from it's physical dimensions. That would be the only other piece of information you would need to figure out what to do.

Hope this helps

So...what tells the relay to turn on and off now? It's hard to tell from your posting, but I suppose something from the relay circuit is getting back into the electronics (?) that drive the relay coil. My suspicion is that it could be noise from the current interrupted by the contacts opening. You might try putting a snubber network across the relay contacts; it's likely to make the relay contacts last longer anyway. As a wild guess, for mechanical contacts, you might try 100 ohms in series with 0.1uF or 0.05uF. STRONGLY recommend you use caps rated for AC service, assuming you're controlling power line levels to the fans. If that doesn't solve it, there are for sure other options...for example, a "non-retrigger" circuit in the relay coil drive electronics that definitely holds off the relay coil drive for a second or two when the turn-off occurs. Might be good to know also if the coil as it stands now is allowed to "fly back" to a high enough voltage to rapidly de-energize, or if there's a diode across it (assuming it's DC excitation) that might be slowing the release enough to increase contact arcing. Another option: use an opto-isolated triac (or a "solid-state relay") to control the fans instead of a relay.

Cheers,
Tom

I assume you are using some sort of transistor circuit
to switch current to the relay, and that the relay is a
DC relay.

The fluttering is caused because the current is being
reduced gradually rather than shut off "hard". In other
words, your circuit is operating more like a DC amplifier
than like a switch. You probably need to bias the transistor
in such a fashion that the crossover from "on" to "off" is
more abrupt.

I agree with Hans. Another simple approach would be to put the output
of the electronics to a flip flop gate. If the ic can't handle the
current of the relay, put in a small relay to control the larger or use
a high current transistor circuit controlled by the ic. Just some
thoughts.

Here's what's REALLY happening:

The switch/sensor circuit is essntially a sort of nonlinear DC amplifier, meant to turn on when the resistance of the temperature sensor changes enough. The trouble with the circuit used is that it is also somewhat sensitive to changes in supply voltage.

You probably have both the fans and the sensor circuit running off the same 12 volt supply. (Stop me if I'm off on this). If so, when the fans are running, they load down the 12 volt supply slightly. Not a big deal. But when the device cools off and the circuit deenergizes the relay, the load of the fans goes away and the supply voltage rises slightly. That rise is enough to change operating conditions in the temperature sensor circuit so that it reenergizes the relay for a moment. Then the supply voltage drops, and the relay deenergizes...you get the picture.

One solution is better regulation of the supply voltage. Another, simpler method is to put a diode or large capacitor in parallel with the relay coil to slow it down. Note polarity - the diode should have its cathode (the line part) going to the positive and its anode (the arrow part) going to the negative. In other words, the diode is installed "backwards" so that it doesn't conduct when the switching

transistor is turned on. If you use an electrolytic capacitor instead, it's plus to plus, minus to minus. I'd try whatever electrolytics I had lying around, as long as they had at least a 15 volt rating.

I built a simple circuit to control some fans. When the temperature goes up the fans come on. However when circuit is about to switch the fans off (by de-energizing a 200 Ohm relay), the relay flutters on and off quickly for a second, sometimes longer. Its very loud and annoying.

How can I stop the relay from "fluttering" like this? Do I just need to add the right value capacitor in series with the relay coil or something simple like that? If I am right, what sort of capacitor / value do I need?

Thanks in advance.

Scott.

90. DDS-driven PLL?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-05 00:50:24 UTC

Hello,

I'm working on a synthesizer that will have a wide range (~30-50 MHz frequency range). Obviously I can't use a DDS to simply generate the whole thing. Now, the DDS's that are available can generate pretty small steps... so if I generate a low frequency range, I should be able to multiply up to the higher, wider range with a PLL, right?

Two main alternatives I'm looking at. I want to cover the range 80 to 110 MHz. I can use the DDS to generate 0.8 to 1.1 MHz, then use this as the reference for the PLL with a fixed division ratio of 100... so my final output range is 80 to 110 MHz. Or, I can use a much smaller range in the DDS, say 0.995 to 1.05 MHz, and use a variable division range in the PLL. A microprocessor would be used to compute exactly what DDS frequency and PLL division ratio to use for a given output frequency. I saw something along the lines of this in an article by Ulrich Rohde about modern receiver design in QST several years ago (which I seem to have lost unfortunately).

Is one better than the other, and if so, why? The first method, on the one hand, seems simplest to implement, since I only need to program one device (the DDS) to get a given frequency.

However, the first method uses the DDS to generate a wider range of frequencies. Will this be harder to filter to provide a good reference to the PLL? With the second method it would be possible to filter the DDS output with a fairly tight BP filter to minimize spurs, whereas with the first method, the second harmonic of the lowest frequency (0.8) is 1.6 MHz, which is only 500 KHz above the upper frequency (1.1) that the filter would have to pass.

Any thoughts? I appreciate any input. Thanks.

I'm no electronic genius. I am learning little by little by playing around though, on my own. The flip flop gate, does this just detect a rising or falling current and close/open another circuit based on the edge? The temperature sensor circuit is 100ma.

Scott.

It certainly is wired to the same 12 volt source. The wires coming into the
circuit also feed the fans (.5 amps).

I recently acquired a TS-1100/U military test set for transistors, circa mid 1950's. It appears to be in good condition, however, on examination, it requires a stack of unusual batteries to power it. I have no idea what they are, or what normal operating voltage is.

I would like to build a power supply so that I can use this instrument. Anyone have schematics?

Thanks,
Pete

Assuming both will match what you want to match then the pi is the obvious choice since you have two caps and one coil. Generally the caps are already set up to have one side grounded.

What I'm worried about is that you may not be able to match the antennas you have on the bands you want to use with either a normal T or a normal PI. Each will match over a different range of impedances. You may also need one of the odd configurations. It's generally better to know that before you start drilling holes than to find it out after ....

As an example using the 80 meter dipole:

At 3910 you don't need a tuner, it's already 50 ohms and probably is close enough to 50 ohms up to 4000.

If you want to tune the 80 meter dipole on the low end of 80 meters through a short run of coax that's different ....

Down there the antenna is to short to resonate so it will look like a capacitor. The output of the matching network will have to be inductive to make up for that. In addition the network will have to do an impedance transform from your low Z transmitter up to a higher impedance.

Assuming you build a PI with the two capacitors grounded and the coil in between them:

With the output capacitor set to zero and the coil set to a reasonable L you may or may not be able to do the match. (With the output capacitor set to zero you actually have an L network ...).

There are all kinds of neat tables and formulas in the various handbooks that you can check out to see if it will work or not.

It's a matter of matching the range of the tuner to the range of antennas.

You can also do things with the length(s) of your feed lines to work out a match as well. You can also simply clip lead the parts together and see if they will do a match into the antennas you have. Clip leads are easy to move around .... :)

Hope this helps rather than confuses the issue ....

Bob

You have it pretty much nailed. Narrower DDS operating ranges are
generally better because they can be filtered more easily.

You could also use a varactor-based tracking filter driven by an 8-bit
DAC to filter the DDS output with a broader frequency range, of course.

I've seen commercial radios that use a DDS followed by a
PLL multiplier. The designers examined the DDS output for
spurious levels, picked the frequency range they wanted,
then followed it by the right multiplier.

I could tell you more, but then I'd have to kill you. :-)

Source record: 55551

NEW PROGRAM: ZOC_ZSC.exe

Measure the input impedance of that unknown length of coax
or twin-line, first with the far end open-circuit and then
with the far end short-circuit, to obtain Roc + jXoc and
Rsc + jXsc. Then enter the measurements into program
ZOC_ZSC along with frequency and measured length of line.

Output data: Zo, Angle of Zo, Attenuation dBs, electrical
length in wavelengths, VF, wire loss, ohms/m, mhos/m, uH/m,
pF/m.

But to obtain more than just Zo and dBs accurately very
accurate measurements are needed. Best to avoid extremes of
impedance at whole numbers of 1/4-wavelengths. Measure at
frequencies where line length is approximately an odd number
of 1/8th wavelengths.

The Zoc/Zsc method can be used to determine the transmission
characteristics of any 4-terminal network used between its
image impedances.

Download ZOC_ZSC in a few seconds from website below. 41.4
kilobytes. Run immediately.

I've always wondered if it might make sense to cascade multiple DDSs,
each clocking the next in turn, allowing for numerous combinations of
division factors at each chip. The driver software would theoretically
be able to pick a set of division factors for any desired output
frequency that would minimize spurs.

Of course, achieving any improvement might be mathematically impossible;
i.e., you simply couldn't do any better than the
single-chip/single-clock case. Haven't really thought it through.

I think that you're asking for serious phase noise problems if you do
that. Even using a DDS output as the reference for a PLL has the
potential problem Laura alluded to: be careful about spurs in the DDS
output. And those spurs will in general be different for each and every
possible divisor...perhaps those who look for them know how to reduce
the search, but you wouldn't want to assume the DDS to be good in a band
just because it was good at one or two frequencies in that band.

DDS's are getting better...I believe you'll find ones that easily cover
the range the original poster is interested in. OTOH, in the 100kHz
region, you can use a 20-bit or even better DAC and get pretty darn
clean signals...to use for PLL multiplication.

There are some examples of really clean, fairly wide range LO
systems...the ones I'm aware of (in spectrum analyzers, for example) do
NOT use DDS anywhere. -100dBc @ 1Hz offset?? :-)

Cheers,
Tom

A snubber (flyback) diode across the relay will protect the driving transistor from the reverse voltage spike (back-EMF) when the field of the relay inductor collapses. Although I am not an expert in this area - I don't think this will necessarily stop the chattering.

Relays normally chatter anyway to some extent (if you look at the manufacturer specs you will see they give guidelines) although for most purposes this would only be for a very short time span and unlikely to be noticable during usage.

The most likely cause I can think of is that there is insufficient decoupling between the transistor driving circuit and the line that energizes the relay inductor (in other words - when the relay coil switches off this reduces the loading, changes the operating conditions which switches the relay on again, and so on).

One way you could try to fix this is with a large decoupling capacitor between the supply lines. This might smooth out changes in operating conditions sufficiently to give the circuit more stability.

Since you mention you are interested in studying more about electronics, you might also consider the effects of the return current from the relay inductor on the voltage potential of the transmitter emitter terminal. Although we tend to think of the 'wiring' in circuits as equipotential (for example, all points connected to ground will be 0v) - this is actually an oversimplification. Wiring will have a small resistance.... and (from ohms law) any current through the wire will set up a voltage potential across the wire.

Look carefully at exactly how you have soldered the emitter and relay grounds to the power source ground with this in mind.

When the relay is energized a relatively large current will be flowing from the relay to ground and setting up a voltage difference across that path or trace.

If the emitter terminal grounding is connected mid-stream on the above path then the relay switching on/off is also creating a small but significant change in the voltage level at the emitter. This might be another cause of the problem.

This effect can be minimized to some extent by keeping the 2 ground lines separate to a point as close as conveniently possible to the battery terminal.

Hope this helps.

Best regards, Roy G0WMF / 7J1AUA

Nope, simply run the relay from a zener diode set at 12 volts. Now when you unload the supply from the fans shutting off, the rise in voltage won't cause the relay to pickup again. The snubber diode should be there in any case to remove the back emf.

troglodite@aol.com (Troglodite)
shared these priceless pearls of wisdom:

->
->>Does anyone ahve any plans or at least ideas on omnidirectional antennas for
->>220 or 440? Something beyond a simple ground plane. Thanks.
->
->A colinear is fairly easy to construct, is omnidirectional,

Maybe I'm being a bit pedantic here, but neither a ground plane nor a collinear
is omnidirectional. They both have gain in the horizontal direction by
suffering a loss in the vertical direction. "There ain't no isotropic
radiators."

Perhaps the original poster could be a little more specific? Like specifying
if he means horizontally omnidirectional while allowing the vertical pattern to
squish down?

A colinear is fairly easy to construct, is omnidirectional, and has between 1.5 and 6Db of gain depending on the number of elements. You'll find it in most of the ARRL handbooks. You need a balun loop to match the feedpoint, but at 220 or 440, this is quite small. There is an example of a 144Mhz design in the handbook, with the info needed to calculate other sizes. For the elements, I've used brazing rod, aluminum grounding wire, etc.

FWIW - Another approach:
Although more complex and expensive, you might consider a PLL VCO and sum the modulation signal into the control port. Have no experience with VCOs in the 50 MHz area, but from your info you are going to at least 150... The bandwith of many UHF VCOs is several MHz. For example: I have built a 900MHZ FM ATV TX (Speak acronym? :) that is modulated by NTSC video summed to the control port. Sure is broad, but works well for the color TV signal. Receive the wide FM using the indoor portion of an old Sat-A satellite receiver (70 MHz input - Video out, whose input is driven by a downconverter). I scrounged the parts from an older 800-900 MHz 3 watt 2-way RF deck.

Probably not as stable as a xtal designed for freq std use. All xtal oscillators are going to be analog, with schmitt triggers and flipflops shaping and scaling the waveform into something we call "digital".

You also have to consider the axis on which the xtal is cut, which affects the resonant frequency, stablity and oscillation characteristics it exhibits.

Henry:

Depending on who's phone you get it out of the TCXO in a cell phone is going to be roughly +/-2.5 ppm over the 0 to 60 C temperature range. If you get one with a bare crystal in it they usually run about +/- 10 ppm over the same range. The TCXO's are fairly flat in the region of room temperature, generally below 0.1 ppm per degree C. The crystals are not as flat ...

Frequencies vary from phone to phone. 12.8 MHz is common as are a couple of other frequencies. They are all odd numbers though. No 5 or 10 MHz even type stuff.

Output from the TCXO will probably be a clipped sine wave. Typical load impedance is something like 1K ohm in parallel with 4 pf. Again, different units have different loads.

Most have a trim adjust on them. As you pull the oscillator out of the radio it will probably be about 3 ppm off frequency and you will have to adjust it against a good standard to get it back on frequency. If you adjust it plan on coming back about two weeks later to re-set it. The tiny little trimmers tend to move on occasion.

Supply voltage to the TCXO will probably be 5 volts in the older phones and 3.3 volts (or below) in the newer phones.

The main difference between the analog and digital phones is that the digital phones are more likely to have a bare crystal in them and no TCXO at all. Again, it's not a hard and fast rule different brands do it different ways.

All in all the TCXO's are useful if you are doing a synthesizer project or something similar. You can't beat them for the price. They are not as useful if you are trying to run a master standard setup.

Probably the best bet for a master standard would be a surplus 10 MHz OCXO. You see them on the auctions and at flea markets for $50 or less. Any OCXO as long as it still works will blow the cell phone TCXO away as a frequency standard. Even if you get a crummy one it should do +/- 0.05 ppm or less.

Hope this helps

Bob

You could hook up the flip/flop and set the following stage to flip or
flop on the edge or not. But the gate is basically a on/off switch.
It turns 5v on or 5v off. If properly set-up there should be no 'in
between'. Its either on or off.

Take the output of the gate. To the following stage transistor or
relay. Simple as that.

FOr a few dollars each, it's worth just buying one and taking a look
yourself. There should be other interesting parts in side besides
a crystal.

One thing worth doing is looking for older phones. The older they are,
the bigger they were. Not only will they be likely to carry a lower
price, since nobody seems to want those old clunky phones, but you
are much more likely to find parts that are re-useable. I've picked
up a number of old cellphones, the first one cost all of fifty cents
at a church rummage sale. That first one was reasonably old, and
while there were surface mount components, they weren't all that kind.
I picked up an even bigger, and presumably older, cellphone after
that, and most of the devices were DIP. I imagine older phones
have the advantage also that integration hadn't become so extensive,
so you could pull ICs out that were useable in other applications,
while the smaller they phones get, the more likely the ICs are
specifically for cellphone use and incorporate all kinds of functions
in larger pin packages.

The 3 or 4 cellphones I've bought at garage sales ahve all had
TXCO's in nice little modules. They all have "odd" frequencies,
intended for binary counters rather than adjusting to match WWV.

But they are also a source of "roofing" filters in the 45Mhz or even
higher range. And since they all convert down to a lower frequency
to demodulate the signal, there will be a crystal to bring that frequency
down to 10.7Mhz or 455KHz, and afilter at that ultimate IF suitable
for narrow-deviation FM. THe FM IF strip is usually a signal IC,
and if one needed such a thing, the whole thing could be extracted
as a module.

There should also be a prescaler or two. And if you find an old enough
phone, a nice and common synthesizer IC.

I think all the phones I've taken apart have an NE570 or derivative compander IC.

They seem to use what appear to be diode-ring mixers, complete in little metal cases.

The cases always seem intriguing, though since they are built to match the circuitry rather than a general purpose box, fitting your own circuitry into the box may take effort.

There will be various CPUs, again the older the more likely to find a general purpose unit, and plenty of CMOS logic, though that may not be of real temptation to someone looking useful scrap.

Hello,

Staying on the subject of oven-ed oscillators - I have a project on the go where I need to control a 10MHz VCXO in a phase-locked loop via a DAC. To help achieve this the voltage range needs to be as narrow as possible and so I intend to use a home-brew OCXO to eliminate that portion of the control voltage change required by moves in temperature.

As a series of these may be produced I will also be using cheap computer xtals. These I believe are AT cut and designed for room temperature operation but to have a fair control over them I'll have to move the oven turnover point up to around 50C.

Any thoughts or suggestions on the above would be most welcome. Seen through my ever-optimisic eyes it all appears to be straightforward but I fear that Murphy will get his fingers in there somehow.

The omnidirectional term applied to antennas is usually understood to
mean that the antenna is mounted near the earth and you are talking to
earth stations. As there were no reasons to send the signals out in
space Untuil the late 1950's) and the signals do not penetrate the earth
to any extend the omnidirectional term applied to the earths surface.
The omnidirectiona term is used in many publications in that sense.
The omnidirectiona term is often used for the patern of a ground plane
or colinear mounted in the clear. Phellps Dodge (the book nearest me)
lists the patern as omnidirectiona for their vertical GP and colinear
antennas , or offset and elliptical to describe paterns if the antenna
is mounted on the side of the tower.

Maybe you should eat the soup instead of spreading it on the page :-)

If you find one old enough, where the parts are fairly generic, you'll
end up with a good portion of the parts to build a scanner, ie the
IF strip, a front end mixer, and some of the synthesizer. But since
the cellphone is only intended to cover a very small segment of
the spectrum, you'll have to come up with a VCO for the synthesizer
and all the front end filtering needed. You won't be able
to make a scanner by a "few simple mods" of a cellphone.

On the other hand, a 45Mhz IF strip out of a cellphone would
pretty much match the output of a tuner from a TV set, so one
could fairly easily make a wide band receiver, albeit with analog
tuning.

I use an NDK 12.8MHz oscillator to control the frequency of
my HB rig. I have also used the Toyocom 14.400MHz oscillator
modules from old Motorola phones. Frequency stability is very
good, about +/- 1ppm, even in my outdoor shack.

Joe,

More or less in order:

1) Do a quick sort on your crystals - rig them in a simple plug in oscillator hooked to a frequency counter. Once the oscillator is going, grab the crystal with your fingers. This will heat the crystal. You only want to keep the crystals that drop in frequency when you heat them up.

2) A simple way to check turn point without a lot of weird test gear - dump the plug in oscillator crystal and all in a glass of very hot water. Works better if you put the gizmo in a plastic bag first :) . As the glass of water cools you can monitor the frequency. You are looking for a frequency dip. A kitchen thermometer will give you some idea of what temperature the whole thing is at. You want to keep the crystals with turn temperatures above about 60C or so.

3) Glue a heater on to the crystal package and match it's temperature to the crystal. Generally this is done by adjusting the temperature of the heater while monitoring the frequency of the crystal.

4) Glue the varicap diode to the heater next to the crystal. It needs to be heated to give you reasonable temperature stability.

If everything is fairly well insulated you should get stability in the low parts in 10-7 range over a 20C change in temperature.

Hope this helps ...

Bob

Robert,

Right now Analog Devices is back ordered on almost every useful part they make. Even if you are buying 250,000 and up type quantities you are having a hard time finding parts ....

Mini Circuits is getting better recently. They are only out in the 6 week time frame on the stuff that was out 16 weeks last summer.

Good luck ...

The ATV community uses an omni directional (horiz. polarized) antenna called a skeleton slot. This is a 440 antenna with some gain, as I recall about 5 dbi. It is not easy to build and a two man job to tune. It may be described somewhere on the net. We used two of them on our ATV repeater.

>I went to the site and read up about ccw but still do not get it. Is it just
>pc generated clinically generated regular cw or is it recoded as data to
>produce speech or what?

CCW synchronizes the clock edges (ON/OFF transitions) at the
transmitter and receiver. This allows the receiver to use an integrate
and dump filter design. The integrator integrates all received energy
during each possible symbol time then uses an adaptive slicer to
decide if the transmitter was on or off during that interval. The
integrator is then dumped, and a new integration started for the
next possible symbol time.

The benefit of this is that it effectively synthesizes an extremely
narrow filter fitted to the exact transmit signal. This offers the best
possible SNR improvement for a on-off keyed (OOK) AM Morse
signal. This allows good weak signal operation.

You can't normally do this sort of optimum filtering with an OOK
AM Morse signal because you don't know when the bit intervals
can occur. So you have to use a wider filter to let in all the possible
modulation sideband frequencies that could exist in the transmitted
signal instead of tailoring the filter for only the particular sideband
frequencies that can exist for any given symbol time.

(The effective filter bandwidth for 12 WPM CCW is 28.8 Hz.
Ordinary manual 12 WPM Morse would need a 66 Hz filter.
This gives CCW a better than 3 dB advantage in noise.)

This sort of synchronous clocking is inherent in some forms of
digital signaling, but not in manual OOK Morse. That's one of the
reasons that the other sorts of signaling often perform better in
noise than manual Morse. CCW levels the playing field a bit.

The output of the slicer can key a local tone oscillator to let you
decode the Morse manually, or it can feed a machine decoder
to convert the Morse to visually or aurally presented text. (The
latter requires text to speech synthesis software on your computer.)

Normally, machine decoding of manual Morse doesn't work very
well. But because CCW is synchronous, machine decoding can
be made to work about as well as is possible for a non-uniform
Code like Morse. It isn't up to the standard of a fully voiced
modulation using a uniform code, but it is quite good compared
to by ear decoding of OOK Morse.

Note that the original version of CCW synchronized the master oscillators of the transmitter and receiver to a common external standard (for example WWV) as well as synchronizing the data bit times. This has been abandoned today because it requires specially modified radios.

It did offer another 3 dB of SNR improvement under stable ionospheric conditions (which puts it only 3 dB down from FSK). It didn't help much under the more usual multipath fading conditions of the 40m and 80m bands, however, and the requirement to modify radios limited the number of amateurs willing to use it.

The instability of the ionosphere is also the reason MFSK can work better than PSK on lower HF (or on polar paths at upper HF). RF phase coherence gets too distorted on such paths for reliable RF phase coherent operation. Baseband coherence is still an advantage, of course, as are the use of fully voiced modulations and use of uniform codes.

Not true. Although a digital gate or inverter might seem to have switch-like
properties, the transfer function from input voltage to output voltage
actually has a substantial linear range. It just seems like it's a switch
because the 'gain' is so high. If you put a 'noisy' voltage into the input
at just the transition point (~1/2 Vcc for CMOS), you'll get a much noisier
output....therein lies the problem.

The best solution is to incorporate hysteresis. Hysteresis will turn a slow
changing and/or noisy input voltage into a cleanly switched output voltage
with no chatter. This can be accomplished with a pair of cascaded CMOS
inverters, with positive feedback from output of the second stage to the
input of the first stage. Drive the input to the first inverter with a
resistor, say 10k. Put a feedback resistor from the output of the second
inverter to the input of the first inverter of say 300k.

Is this easier than using a Schmitt trigger like an 'HC14?

Alternatively, it may be more convenient to use a comparator
(like an LM311 or more modern variant) with hysteresis.

I have an AR88 LF with badly damaged trimming strips adorning its front panel.

They show only small fragments of the silvery plating left on them. The base metal is copper coloured, and is showing through.

Can anyone confirm the types of base metal and plating for the trim strips?

Has anyone got tips for the restoration of these strips? The radio is worth some effort to restore it cosmetically, as it plays well since I re-capped it last year.

Any constructive help greatly appreciated.

The particular one I'm thinking of is in the HP-3588 (and 3589, too, I'm sure). I picked one up at an employee auction. Somehow though we made them where I work, I'd never used one for anything other than a casual measurement. So...I hosed a good reference oscillator into it (HP-10811) to see how good its resolution was. The whole system of the reference osc and the analyzer showed -100dBc at 1Hz offset. I was surprised...but on talking with a couple of the designers who had worked on that instrument, I was assured that my measurement was "real." AFAIK, it is a two-loop system, designed by a pretty darn sharp guy.

I suppose we have some signal generators that are similarly clean. I haven't measured it (with an independent analyzer) but suppose the source output of the 3588 is also clean. But I also expect that it doesn't go terribly much further down that 100dB since that's the range of the analyzer, nominally.

Cheers,
Tom

A long shot here - are you aware of any "substantially omni" (in the
horizontal plane) horizontally polarised antenna capable of 60-600
MHz? We have a problem situation with TV transmitters subtending >120
deg and no conventional TV ant is worth a rats a####. The local TV ant
floggers have no ideas, as is the case with the broadcast engineering
firms. As a recently retired comms engineer, I have not come up with
any ideas, and would welcome any comments.

151. Re: Plans for onidirectional antenna for 220/440

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-08 07:38:09 UTC
From: w1eof@aol.com
Message-ID: <20010108023809.29958.00000497@ng-cb1.aol.com>
Source record: 55598

Ultimately I am looking to build a vertically polarized omnidirectional multiband antenna similiar to the commercial versions like the Comet. They seem to be some sort of colinear array that acts like a ground plane on the highest band. This is for casual repeater use on 2m/220/440 with one coax running down into the shack.

Less desireable although still of interest would be single band antennas.

Thanks

Mark W1EOF

I can't tell you what the specific impurity is, but I can tell you that the stuff works very well. I had a circuit with a fuse in clips on a circuit board, and the current drain was such that the fuse got hot enough to unsolder itself on it's end. This was due to the voltage drop in the clip. I coated the clips with CoolAmp and the problem disappeared.

No not really, our efforts to come up with a decent Omni horiz antenna met with poor results at best. Not having a true antenna test range to test the rib cage design I would say it did give us Omni coverage but little if any gain and the bandwidth was very narrow.

There are two Cool-Amp products, one is the silver plating powder, applied with a moist rag and lots of buffing, and the other is the paste form, which looks like silver powder suspended in a light oil. I have used both, and suspect what Doug was using is the paste. That doesn't take much rubbing.

I still don't follow exactly what is needed here, but here's a
thought...
What about four real cheapie (ie low gain/broad pattern) VHF/UHF
TV antennas each pointing at 90 degrees from the next one? I've
seen some low-power TV installations using this scheme.

Bill. In the "old days" that was the type of approach used, through a
master system with individual channel filters to avoid significant
ghost (etc) addition. That was feasible - albeit expensive for
domestic use - because our TV channel allocation plan deliberately
avoided adjacent channels in any service area, and filter cutoff (er,
rolloff) was not a major issue.

As of 1/1/2001 (hey, that translates into US just fine) all that has
gone west. All the vacant "buffer" channels are now used for parallel
digital transmissions, so everyone's IF has an adjacent channel
rejection problem which tey were never designed to handle. This
complicates the reception of EITHER analog PAL or digital. As a first
step towards getting the reception quality backup a bit, I was
starting at the input where a set of rabbit-ears have worked
acceptably in the past.

Please don't tell me that antennae won't address an ACR problem - I'm only too well aware of that. But the ACR and the original levels of ghosting etc caused by antenna azimuth alignment problems are together making the picture substandard. I can't readily fix the ACR but I can focus on the az problem. I hope that explains where I am coming from.

Message-ID: <23627-3A5AA052-41@storefull-154.iap.bryant.webtv.net>
Source record: 55618

Anyone have a suggestion for a simple way to use heterodyning to achieve a difference frequency whereby 800 MHz signals would then appear in the 400-500 MHz range? As a real newbie, I am hoping that some simple oscillator can be bought or made, one which would produce the requisite frequency. I'm not looking for anything sophisticated, because the kind of things I consider fun have been listening to shortwave broadcasts by intermodulation on my AM radio by just wrapping a long wire around the set. Also, I've used a scanner with a 10.8 MHz IF which picked up both upper and lower images very comfortably, so I would think the idea should be fairly simple.

> what the impurity would be? Would it affect the conductivity?

There are various copper salts produced in the plating reaction than can be trapped in the layer. They will decrease the conductivity slightly. For best results, the silvered surface should be rinsed thoroughly in clean water to remove most of these salts.

Cool-Amp puts down such a thin layer of silver it hardly improves the RF conductivity of clean copper. However the silver surface does not oxidize or corrode as readily as copper so it maintains its RF conductivity longer.

One thing that has not been mentioned about silver in switch contacts and such is that the silver oxides and sulfides are easily rubbed off the silver surface by mechanical contact (you could not polish silverware with a cloth if the tarnish clung as tenaciously as copper oxide does to copper).

If you have a clean copper conductor that you can protect mechanically from surface oxidation and corrosion (like with a coating of clear acrylic spray lacquer), silver plating with Cool-Amp will do little to improve the situation.

Asunto: Net-abuse from your user PHIL DRAGOMAN

##
For the Attention of the Net-Abuse Service.
##

The user Phil Dragoman (Road Runner) is commiting net-abuse again and
infringing the Acceptable Use Policy for AT&T Road Runner Newsgroups.

He keeps sending libellous, sexual, offensive and racist Usenet posts.

Please find enclosed his last offensive posts (these posts are about
fucking the mother and father of Spanish citizens, and he use to employ
terms like: whore mother, asshole, bitch, fuck, etc. This is a sample of his
Usenet post using Road Runner:

Phil Dragoman <phil.dragoman@literally.com> escribi&#65533; en el mensaje de
noticias 6kv26.21303$1M.4882122@typhoon.ne.mediaone.net...
>Vete tomar por el culo, tu hijo de la chingada. Chupa la polla de tu
> padre. Vete darle el beso negro a tu madre, t&#65533; mula. T&#65533; cobarde
> sin pelotas. Perro sin honor. Mr. Nobody.
>
> Phil
>

The translation into English is:
"Put it up your rear end, you son of an indecent woman. Perform fellatio
with your father. Lick your mother's anus, you she-mule. You are a coward
without testicles. Dishonourable dog."

Another post attached below says:

Phil Dragoman wrote: CHINGA TU PUTA MADRE
(Translation into English: FUCK YOUR WHORE MOTHER)

Yet another post attached below against a Spanish citizen below says:

>Phil Dragoman wrote: "Ahora puedes hacerse puta tu mismo. Viene de
familia, &#65533;no?"

Translation into English: You can become a whore now, since all the women of
your family are whores.

##
I have informed of this NET-ABUSE
against Spanish Citizens to the Spanish Government
and to the Spanish Authorities.
##

Please, take the proper action against this deranged user, he use to call
himself a "former politician" in his posts to Usenet.

Regards,

RAC
SPAIN

Jim,

It's cheaper to buy an unblocked scanner from Europe or Canada and
listen to analog cell phone calls that way.

Budgie...
I'm still not sure what the application is. I'm guessing its home TV reception and from what you describe, the transmitting towers are scattered about on hilltops around your location which apparently is in a valley.
BTW, I'm a cable television engineer by trade, with 27 years experience.
First question would be, why don't you simply use a rotatable antenna, but I suspect your answer is going to say that ACR is still the bigger problem.
Here in the states, and I would assume in VK also, since our TVs come from the same source, adjacent channel capability is not normally a problem. It was up until about 10 years ago, tho. If the tuner is being hit too hard with RF, any number of things can occur and adjacent channel interference would most likely be occuring there, not in the IF. Similarly, if the adjacent channels are drastically different in levels, bleedover (cross-mod) could be expected. If you're only a mile or two from the transmitters, overload across the board is a very likely possibility.
Take the typical cable TV scenario where you dump 100 adjacent channels into a TV set. It works because the individual signal strength on each channel are somewhat equal, and the total power being delivered is within the range of what the TV tuner can handle.
Now, the approach to deal with with your 'all-adjacent' off-air situation will vary depending on who you are...a normal domestic viewer or some kind of commercial installation.
The obvious first step would be to see if a simple attenuator, maybe 20db or so, would improve the situation. And I would be re-miss to not mention the possibility of a faulty tuner creating these problems for you. If not...
The least expensive way to deal with it would be to simply install traps inline to notch out the new digital channels, unless you have a current need for them. These traps cost about US$8 each.
If you do want to receive ALL the channels, the approach would be to simply split the incoming line via a 2-way splitter, use traps to the digital channels on one side, and the PAL channels on the other. Then you could use a A-B switch to feed the TV set.
Even that is a bit much for the average TV customer, but it seems

you have a very unique situation there. They are dropping in the digital channels in a similar way in the US but I don't hear much about the problems created by it...yet.
If its a commercial installation, single channel bandpass filters are readily available that will reject adjacent signals. In that case, split the antenna(s) feeds accordingly, use the filters to isolate each one, attenuate to get equal levels and mix'em back together. Actaully simpler, but considerably more expensive than the 'home' version mentioned earlier since decent bandpass filters start at around US$125 each.
If you can beg, borrow or steal a cable tv signal level meter you can better see what you're up against. You could have something like one single channel being present at a significantly higher signal strength that is driving the tuner into distortion and that could be the only one that needs attenuation. I had a situation like this where a local FM station drove our equipment nuts.
Its an interestion scenario. The powers-that-be made the decision to occupy adjacent channels based on the concept that TV receivers are now capable of dealing with the problem. But, I suspect these decision-makers get free cable service and haven't had to mess with a TV antenna in many years. Which is another good option!
Good luck,
Bill Meacham

175. Counterpoise Question

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-09 13:09:54 UTC
From: J Titcomb <kimoloka@hawaii.rr.com>
Message-ID: <C4E66.61170$Z36.434779@typhoon.hawaii.rr.com>
Source record: 55621

This is going to sound dumb, but here goes anyway. Are the radials supposed to be connected to the base of a vertical antenna, or do they just radiate out from around the base, but are not actually physically connected? Its hard to tell from a schematic diagram. Sometimes it looks as if they are actually connected to the base of the antenna. If the radial system were to be connected to the base of the vertical, and if one were to make a homebrew vertical antenna fed with coax, would one solder the shield to the radial system, and the center connector to the vertical portion of the antenna? That seems like a short to me. Thanks

> That seems like a short to me. Thanks

The radials aren't connected to the "antenna". The quarter-wave
element is connected to the center of the coax, and the radials to
the shield.

178. Capacitor Question

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-09 19:11:40 UTC
From: rcnixon@mindspring.com
Message-ID: <3a5b60e3.15705188@news.mindspring.com>
Source record: 55624

I have come into posession of some 14,000 ceramic disc capacitors. They are all 50 VDC, 5% units ranging from 1 pf to 880 pf from the same manufacturer, KCK. They are neatly put up in bags of 150 but one thing puzzles me. The label for each bag specifies a "Char." which I guess means characteristic. For instance, I am looking at a bag of 470pf, 5%, 50 VDC with "Char." VK. There are other "Char."s as well but I am too lazy right now to go look.

Does anyone have any idea what this means? If necessary, I'll get the other types of "Char." for comparison.

Russ Nixon - KF4WXD

You need to specify if you are looking for ferrite material, or iron
laminations. That should help narrow down who to recommend.

184. High grid curernt on sb-220---help

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-10 00:58:57 UTC
From: antennas_ca@my-deja.com
Message-ID: <93gc4fkeg1@nnrp1.deja.com>
Source record: 55630

I have an sb-220 that seems to have had the bandswitch in wrong
position. Only worked well on 10M. Then as you go down in freq it
worked worse and tubes would get red really fast on lower bands. SO I
was looking at the switch from the schematic and it wasn't right. So
moved it so it was same as schematic on 80M posn. Ok now seems better
but have very high grid current on all bands.
Is there another mismatch in the oputput circuit? What would cause the
high grid current??
Thanks for all replys. PLease email to me at antennas@yahoo.com

Fairly close - I'm actually on the same escarpment, elevation here is
about 20m less than the Tx sites. I look UP because theya re tall
masts and towers :-)

>BTW, I'm a cable television engineer by trade, with 27 years
>experience.

Somewhat similar - a (just retired) RF systems engineer of over 30
years, mainly from two-way radio areas.

>First question would be, why don't you simply use a rotatable
>antenna, but I suspect your answer is going to say that ACR is
>still the bigger problem.

Rotatable will address the ghosting issues due to a single-azimuth
antenna, but yes ACR is the (new) problem. For example (and I'm not
sure of your bandplan) we have 6 174-181 MHz thru 12 as contiguous 7
Mhz slots. Our analog bandplan had 7, 9 & 10 in common service areas
with 6,8,11 in low population areas, as well as some in 88-108 before
FM. Most of these 6/8/11 services have migrated to UHF over the
years. Between 9 & 10 was a 2MHz buffer to avoid ACR. The designed
ACR of TV/VCR presumably degenerated to the minimum required in this
environment.

Now we have digital duplication of existing PALs - 6D=7A, 8D=9A,
10A=11D and 12D = 2A if that's clear. So every PAL now has an
occupied channel each side.

>Here in the states, and I would assume in VK also, since our TVs

>these problems for you. If not...

Two TV's, two VCR's - all have same problem whether external or
internal antennae used. Have tried 20dB and 40dB pads to no avail -
it only avoids the herringbone which was visible on one channel under
one circumstance.

>The least expensive way to deal with it would be to simply install
>traps inline to notch out the new digital channels, unless you
>have a current need for them. These traps cost about US$8 each.

I'd like to find traps at that sort of price to notch out a single
channel without adjacent degradation. Nothing like that seen here.

At the indicative price of DTV's here (~$A5K up) and identical program
content, I can't see me wanting digital channels until the parallel
period ends on 1/1/2008, and then the analogs shut down overnight. I
mean. the only benefit (apart from a ?crisper pic) is 16:9 aspect
instead of our PAL 4:3. Big deal :-)

>If you do want to receive ALL the channels, the approach would be
>to simply split the incoming line via a 2-way splitter, use traps

Yes, I have used that sort of system here in the past for MATV
distribution systems. Definitely overkill for the domestic situation
though.

>If you can beg, borrow or steal a cable tv signal level meter you

>decision-makers get free cable service and haven't had to mess
>with a TV antenna in many years. Which is another good option!

I have a decent spec-an ex my RF work here, and levels are not
dramatically different. After years of looking at analog Tv on the
spec-an, it's interesting to see the digital signals - just an
elevated noise floor.

Hello:

I recently picked up a TS-1100/U military transistor tester (circa 50's?). It looks to be in good shape, except that it appears to use some strange batteries.

I would like to rig up a supply for it, but I need schematics. Anybody know where I could find 'em?

Thanks,
Pete

Iron laminations.

In fact I'm interested in winding some transformers for an all s/s AM
modulator.

A local company suggested my prototype 25-30w audio power handling
tranny would weigh-in at around 25 lb, (10Kg). Ouch!

I did not ask the cost.

>
> Doug Moore KB9TMY

I'm not doubting your experience but I find it hard to believe
that simply silver coating the fuse clips fixed the problem.

The reason I have a hard time with this is that I had a similar
problem with a power supply, some years ago. The power supply
was 10 Volts at 500 Amps and ran from a 208 - 3 Phase power
source. It had three 20 Amp fuses on the power input, that
would burn up regularly. The fuses were the common BUSS type.
It turned out that the problem was fixed by replacing the
fuse holder with a different type. On the original fuse holder,
each end piece was made of two parts, the clip and the solder
lug. They were bound together with a brass eyelet. The eyelet
connection presented a small resistance and caused the fuse
holder to heat up. The fuse holders were replaced with ones
that had a single clip/lug construction and the problem
went away.

It just may have been that your fuse holders were the two part
clip/lug construction and the silver coating fixed the junction
resistance problem.

Well, just my $0.02.

I am trying to match some crystals for a crystal filter. Since my frequency counter doesn't have adequate resolution (10Hz), I was thinking I could tune my transceiver to the frequency of my test osicllator and then measure the audio output frequency as I test the crystals.

Can anyone recommend a sound card frequency counter that can offer 1hz or better resolution? There are lots of great programs that provide spectrum analysis but I have not found anything that has adequate frequency resolution for my needs. Thanks.

->
->I'm not doubting your experience but I find it hard to believe
->that simply silver coating the fuse clips fixed the problem.
->

The solvent in CoolAmp to keep the silver in suspension also acts as a marvelous cleaning agent. My suspicion is that it cleaned enough of the hi-resistance crud off the fuse clips to account for the miracle. A can of Rat Shack tuner cleaner would probably have done every bit as much to solving the problem.

Perhaps you could write one? It sounds like an interesting project.

I can think of two approaches, and I'm sure there are others.
Either use progressively longer FFTs to zero in on the frequency
you want, or count zero crossings.

If you really want all three bands on the one antenna, it's hard to go past a discone.

But broadbandedness is about the only virtue that the discone has - it probably uses
as much metal as an antenna for each band.

A 1/4 wave for 2 metres will work in a pinch on 70cm, but if you want something that's
not a compromise, monoband antennas are the way to go, especially for the home constructor.

Though I've never built one, I'd suggest some form of coaxial cable collinear.

I'm looking for the spring clips that were used to tap an inductor coil.
The clips do not have screws in them but you can squeeze and open it like an
alligator clip and place on inductor wire. Mueller used to make them but
apparently hasn't for several decades!

Also does anyone know of a source for roller inductor center forms/insulator
and the associated hardware?

Thanks...

Check out the Arrow J-Pole, http://hometown.aol.com/Arrow146/j-pole.html

he give's the dimensions right on his page... he offers a 220 and 144/440 version.
I'm not sure about combining them into a single tri-bander though. They are simple enough to build from aluminum stock available at home depot.
But at his prices, you won't save that much.

I have the 144/440 dual bander, it works great.

Source record: 55498

In a pinch (oooh, sorry), you should be able to modify standard alligator clips. You could file or grind the "teeth" down, and leave a notch for the wire out toward the tip of the clip.

Another device that should work is something like the "minigrabber" from Pomona, or the really cool clips that you see at http://www.parrot-invent.ro/ (I have some of the latter as voltmeter leads that I like a lot, though I caution about some safety issues using them at high voltage.) I guess it depends on how big the coil wire is and its spacing, and how short you need to keep the wire going to the clip.

Cheers,
Tom

=======
Bruce , Fluorescent bulbs with an electronic starter are readily available
as instant replacement for normal filament bulbs , 230 V in Europe ,Africa,
Asia ,Autralasia and 117 V for the Americas.
They are obviously more expensive than normal light bulbs ,but consume a
fraction of the power.
A 13 W fluorescent bulb gives the same light output as a 75 W filament bulb.
The life time is approx 8000 hrs versus 1000 hrs for a filament bulb.
I can imagine that the equivalent LED bulb (for AC voltages) is much more
expensive at this time, but would be an excellent alternative for 12-24 V DC
systems resulting from Wind and Solar Power.

So the solution for your high cost power ,at this time ,would be the
instantly available Fluorescent Bulb .
I have have seen models from General Electric in the USA.

A very good place to start is http://www.fix.net/dans.html and they have the variable caps and also Ball reduction drives (but the reduction units aren't cheap)...but the other parts are so cheap and he has many values available. It's where I do at least 90% of my homebrew project shopping.

209. DDS board and parts.

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-12 01:34:07 UTC
From: novatech@eskimo.com
Message-ID: <93lmuf$as8$1@eskinews.eskimo.com>
Source record: 55506
Cross-posted to: sci.electronics.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.boatanchors

We did our annual inventory and decided that we have too many of our DDS3 boards and parts. These older DDS solutions are now rather mundane compared to the 100MHz newer parts.

We are going to sell off the boards, a kit of passive parts (plus voltage reference and high speed DAC) and the 33.554432MHz crystal. It looks like $35 ppd. in the USA would be the right price.

You will have to furnish a Qualcomm DDS chip (Q2240I-1N) and a smattering of other parts.

The data sheet is at: http://www.novatech-instr.com/dds3.html

Anyone interested?

Thanks,

Steve.

Source record: 55510

Most amateurs go one of three routes when building a repeater: Convert an older commercial rig such as a GE Mastr II, Motorola Micor, or Mitrek. This is the most popular method if the machine is destined for a crowded hilltop site that requires a high degree of RF immunity. There are instructions on the web. Check out the SEITS site at http://www.seits.org/ but there are others. Punch "repeater building" into your favorite search engine.
Another common method is putting together modules from advertizers in the back pages of QST etc. This is a lot of fun, but don't generally end up being as robust as commercial gear. The final and most expensive method is to buy a commercial repeater from ICOM, YAESU, Motorola, GE etc.

Keep in mind that that the repeater itself is the easy part. You must also add duplexers (or significant vertical separation...not a method for the faint at heart), power supplies, feedline, antenna, and the most important part: The SITE. The whole thing goes together to make a repeater SYSTEM. Remember that the system is only as good as its weakest part.

Have fun, and be prepared to learn A LOT!

214. Re: Mixer Diodes - Homebrew Spectrum Analyzer

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-12 06:37:19 UTC
From: vincent coppola <vinyc@snet.net>
Message-ID: <3A5EA61E.7EF21BED@snet.net>
Source record: 55511

I went through this about 10 years ago when I uncovered an old HP8551 hybrid spectrum analyzer. It of course had a blown mixer diode among other problems that I managed to repair. It is a very old clunker, tubes, backwave oscillator, which was converted to a YIG oscillator though which was nice. It had a range of 10 mhz to 40 ghz with the proper waveguide mixers.
But I still had to solve the mixer diode problem as the original diode , I am not sure it exists on the face of the Earth anymore.

I ended up stuffing a modern day 1n5817 ($1.00 Digikey) shottkey diode (spelling). Believe it or not it worked very well up to at least 4 ghz or so. Beyond that range, like around 10 ghz, I used waveguide mixers and didn't need the diode up there. I am sure other shottkey diodes would work fine also.

No, it was not accurate to the a flat 1/2 db as the original spec., but for amateur radio uses it worked out just fine for me.
I still have it!

Good Luck,

Vince N1VC

When taking multiple readings of the same signal, the display may
flicker between say 630 and 640 Hz and if about 1/3 of the readings
are 640 Hz and the rest are 630 Hz, you could (g)estimate that the
true frequency is little over 633 Hz.

>What frequency are you trying to work at? I have several excellent HP
>counters available for less than $100 that offer resolutions less than
>1 Hz.

These counters must either use a counting time much longer than 1 s or
they are measuring the period and calculate the inverse in order to
display the frequency.

For low frequency measurements any counter capable of counting
impulses can be used. A simple circuit is needed that will isolate a
single full cycle (e.g. falling edge to falling edge) and this signal
can be used to gate e.g. a 10 MHz oscillator into an impulse counter.
From the impulse count the frequency can be calculated. The frequency
can be measured to a large number of decimals in one signal period
time, while using an ordinary frequency counter would require minutes
or hours to get the same accuracy.

Are you looking for schematics to build the transmitter, receiver, controller, etc. or are you looking for a diagram of how to hook everything together? If the latter, you need to know what transmitter, receiver, controller, etc. you will be using and schematics for those so that you can find points to activate the COR, etc. I would start in the ARRL handbook for general info. You might also try Hamtronics at http://www.hamtronics.com/ to see what they have.

But the spectrum of fluorescents - even daylight bulbs (5500K)- is just awful, and I mean awful. Don't believe me? Take a picture of your workshop with ordinary film. You need a lot of magenta correction and even that doesn't get it right.

UltraBrite LED's -- a 3000mcd Agilent blue LED still costs around $1.50, greens are a little cheaper. I don't like the spectra of the white LED's I've seen, so RGB would be the way to go. It would probably cost around $100 USD.

There are a couple of issues to consider here. Firstly, beware of
comparing the results of taking a picture with what is seen with the
human eye. While some film may approximate the spectral response of
the human eye, often the film is sensitive to light wavelengths
outside the response of the human eye. Thus, if the light has a
strong ultraviolet or infrared component, then the film may record
an image totally different than what the eye sees.

Now, having said that, there's also the issue of the spectral response of film inside the passband of the human eye's response, and the issue of the spectrum produced by fluorescent lamps. While the light produced by a incadescent filament is roughtly flat, although more intense at the red (and, especially infrared) end of the spectrum, the light produced by a fluorescent tube may have significant nonlinearities in the light output spectrum. For example, a fluorescent tube may have emission spikes in the red, blue, and green portions of the spectrum, instead of having a relatively flat emission as an incadescent filament would. One of the reasons for this is that a fluorescent light operates by electrically exciting mercury vapor, which emits ultraviolet light (I used to be able to quote the predominant wavelengths emitted, but it's been too long since I've worked in the optics lab.). The ultraviolet light is then used to excite a mixture of phosphors which line the inside of the tube. These phosphors then emit light. The problem is that the phosphors typically emit only a certain specific band of wavelengths. The usual approach is to blend different phosphors together to approximate a white light. But, this is only an approximation.

Some of the problems with the mixed phosphor approach is that the appearance of objects which have a sharply defined spectral reflectance may appear different under fluorescent light. I'm sure we've all heard about clothes that look one colour under incadescent light, yet look different under fluorescent light. Another problem is that as the phosphors age, their efficiency may change. Thus, the spectral output from a fluorescent tube may shift with time. And, finally, the spectral response from a fluorescent tube driven from the AC line varies at 120 Hz (twice the line frequency). Not only does the light output vary (e.g., flicker), but the spectral response varies, too, due to the varying persistences of the different phosphors in the mix. Try placing a rotating object (e.g., variable speed fan) under a fluorescent light and observe the colour bands that appear at certain rotational speeds.

Note, of course, that the spectral output from a fluorescent tube may be varied by changing the mix of phosphors. The major manufacturers have several standard blends, some of which have names like "Cool White", "Daylight", etc. But, they can also make custom phosphor blends. I've seen fluorescent lamps which produce a variety of colours (green, yellow, red, blue, etc.).

Personally, I tend to like a 'blueish' fluorescent (I have a 'pinkish' one on my desk, and I severely dislike it.). Plus, I've not been overly impressed by the fluorescent screw-in replacements for incadescent bulbs. I think the manufacturers have opted for a phosphor blend which approximates the red-ish hue from an incadescent lamp, while I'd much prefer a bluer spectral emission. But, that's just my personal opinion.

However, having said this, I'm not sure that a white LED will be any different than a fluorescent tube. The way white LEDs operate is very similar to the way fluorescent tubes operate. In operation, the LED chip produces an ultraviolet light. This ultraviolet light is used to excite a mix of phosphors, which then produce the 'white' light. Thus, the white LED has the same limitation as fluorescent tubes with regards to spectral purity.

Plus, I'm not sure the light produced by an array of RGB LEDs would be that much better than a fluorescent tube. One advantage is that you could control the RGB spectral components dynamically. However, given that the emission spectra for LEDs tend to be even narrower than for phosphors, I'm not sure the spectral response would be desirable for use as general illumination. Plus, given that the response time of LEDs is much faster than the persistence of phosphors, the flicker problem may be much worse if the illumination device is operated from anything except pure DC.

I haven't addressed efficiency issues at all here. I do remember that incadescent lamps are extremely inefficient (I want to say the visible light amounts to about 4 percent of the energy put into the device, but it's been a LONG time since I've studied this.). Of course, the efficiency can be improved by running the filament hotter so that it produces more visible light, but at the expense of a severely reduced life. Fluorescent lamps are significantly more efficient in general, but a lot of this depends upon the particular mix of phosphors as well as many other issues. I don't remember the efficiency of LEDs, although I think it's improved in recent years. Of course, there are also mercury vapor and sodium vapor lamps which have rather high efficiencies if you can stand the spectral issues associated with them.

Dave

P.S. Standard Disclaimer: I work for them, but I don't speak for them.

221. Macrovision Removal Device

Another approach is to build a counter. There are quite a number of PIC based counter plans on the net. These typically take only $10-15 in parts, and can count into the 60 MHz neighborhood. Most can either count for a full second or have their software modified to do so, giving 1Hz resolution.

I recently built one of these critters and was surprised how painless it was. I wanted a counter for decades but kept putting it off. I actually ripped off ideas from several circuits and put together my own, but most are pretty similar. For your purposes, any one of them would work. Check out http://www.qsl.net/om3cph/new.html or look through some of the PIC project pages - there are many choices out there.

Fluorescent lights for replacing a regular bulb look very good on paper. They have a long lifetime, low energy consumption. I tried a couple of those. They were very expensive too. First problem was radio interference across the spectrum. Had to turn lights off for dxing. Second problem, the lights failed after two months. (GE brand). So much for the efficiency and greatness of these things. VE3MAL

re: Manual Down load on the Swan - Siltronix 1011 web page

Hello there,

I've revised the free Owners Service Manual file formats to provide jpg
gif and pdf down loads. If you've tried without luck to down load the
large original file, these smaller zips will do the trick much better.

Also have a look at the killer new pictures of the original 1011 prototype
tranceiver.

cheers
skipp

This sounds like an interesting project, I hope you will keep us informed
about the results. Do you really need to match the crystals to within
1Hz ? what is the Q of the crystals ?, what is the filter BW ? will a
1Hz error have any effect on the filter performance ?.

If you intend to use this filter in receiver, you can use a spectrum
analyser program and a broad band noise source (reverse biased
Zener diode) to make a nice plot of the filter pass-band. I use
the excellent, 'Xanalyzer' program for Linux. I'm sure there
are similar programs for Windows and the Apple Mac.

How wide (MHz) could one reasonably make a VCO in the
100 to 150 MHz region? I need to cover a 30 MHz bandwidth
around 110 MHz or so. Is it better to use several VCOs?
Could three 10 MHz bandwidth VCO's cover this region with
reasonable Q and noise? Thanks.

Rob

It would seem a simple problem if you can get the specs of the old mixer diodes. Just look up the specs of a new diode type!

However, since you say "this is only ham radio", why not replace them with some fast mixer diodes from someplace like Dan's Small Parts?

I'm pretty sure a 1625 is just an 807 with a different heater voltage, but
I'd verify that with someone else first...

The 1625 is indeed identical to the 807 except for 12.6 instead of 6.3 V heater and a different base. Swapping requires surgery to change the socket.

This goes way back so this is all from my fuzzy memory and could be wrong.

The 1625s are "beam-power tubes" and have beam forming plates connected to the cathode. As I recall, the leads were connected together outside of the envelope, inside the base. The modification involved removing the base and disconnecting the beam forming plates from the cathode and (I think) connecting them to the screen.

If this was not done, there was significant coupling from cathode to plate when the tubes were operated g-g.

The 807s didn't have the beam forming so they should work unmodified. Just be sure the heater voltage is 6.3 and not 12.6.

That said, I question what the intermodulation distortion performance of these tubes would be and the advisibility of operating the amp in today's crowded bands.

This whole thing was mentioned in QST for July 1968, which was reprinted
in the last ARRL SSB manual. "Sweep Tube Linear-Amplifier Design" by
Doug DeMaw.

It's about other things, but it starts:

"It wasn't too many years ago that some of us who were ssb experimenters
learned that a buck could be saved by "operating" on certain brands of
1625-type tubes, thus making them suitable for use in grounded-grid
amplifiers. It was necessary to saw a window in the tube base, locate
and separate the cathode and beam-forming plate leads, and bring them out
to individual base pins. At roughly 25 cents apiece, surplus prices, it

was no strain on the pin-money fund to put four of them to work in parallel and run them at approximately 500 watts DC input."

An octave (2:1) is easily doable with the proper circuit topology and varactors, but the limiting factor might be noise. The larger the tuning range, the bigger a problem you'll have with noise. This will be especially important in receiver applications.

I'm contemplating building a 2M dedicated packet radio
(ie, the modem would be internal). It would probably just
use a crystal (although I guess for FM step sizes a simple
PLL wouldn't be too tough), and possibly one of the receiver
IC's that have onboard FSK demodulators. Does anyone have
any experience using these sorts of ICs?

==========
Bob ,If you build a dedicated VHF -FM radio for Packet ,go for a direct varactor modulator and tap the rx signal directly from the rx discriminator . In this way you will be able to achieve comms of 9600 Baud (and higher). Even if you intend starting with 1200 Baud , make your home brew trx suitable for 9.6K from the onset. You won't regret it.

Good Luck

73 Frank gm0csz.kn6wh@ukrs.org located in Scotland.

Any sort of feedback is legal. Dacs are often used-- somethings
for coarse steering-- and then an analog loop takes over, but it
can be all digital if the "granularity" is okay in the situation.
DACs are often used in slow tracking loops also, like GPS 1pps
loops.

Hi Wes,

Pretty good memory Wes, but the some of the old surplus 1625s were
constructed as you say, but some were not...T here was a way to tell
which was which without disassembling, It's been too long and I have
forgoten... The only reason I recall at all is I built one of those
amps. However, that was in 1958 and old age has set in.

No, they had the BFPs as well, since they were identical other than
heater voltage to the 1625 (actually the 807 came first). -- don't know
if there were also 807s that brought the BP lead out of the press
separately and joined it with the cathode lead in the base. If so then
they should be useable (modified) just like the 1625s. I do have one
807 that has a large hole drilled in the bottom of the base, as if
somebody were exploring the wiring inside.

Well, that's what it remembered too until I looked in my 1962 ARRL handbook. It shows two different pinouts, one (5AW) for the 807 and another (5AZ) for the 1625. The 807 doesn't show a suppressor grid (beam former) as does the 1625.

I guess that's why we drank 807s but not 1625s.

252. Pi_L PA Output Network Design

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-14 02:32:51 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <93r3gcegq4@plutonium.btinternet.com>
Source record: 55449

NOW AVAILABLE:

NEW Program "Pi_L_NET.exe"

Pi & Pi-L OUTPUT NETWORKS FOR RF POWER AMPLIFIERS.

The program is in two parts. For given RF power output, RF plate/anode/collector volts and external load resistance, the first part computes either the L and C component values of a Pi-L network or of a simple Pi network.

The second part allows the L and C values to be varied in fine increments while observing how the input impedance of the network varies. The network input impedance is the load presented to the amplifying device: triode, tetrode, bipolar transistor, FET, etc.

In particular the input impedance can be observed as the tune and load capacitors are varied as in an actual amplifier. Or as frequency is varied off-resonance up to harmonics of the carrier frequency.

The program can also be used to compute L and C component values of Pi or Pi-L impedance matching networks between any two resistances. The phase delay through the network can be specified if needed for particular applications.

File size = 50 Kbytes. Download from website below in a few seconds. Not zipped up. Run immediately. Absolute bargain.

Bruce,

I wish I could get a spec sheet on the old diodes. If I could then as you point out the problem of substituting for them would be a lot easier.

The consensus seems to be that almost any microwave shottkey mixer diode will probably work. Most have reported a couple of db or so degradation in performance.

What I keep hoping for is somebody who is/was involved with the instrument and who just might have the "silver bullet" answer (as in "use a HSMP XXXX it's exactly the same die ...").

As you point out the cost of the diodes is pretty darn small compared to the cost of the analyzer. The real cost is in my shaky old hands butchering the job of swapping the diodes out. If I was better at fiddling duroid boards I'd probably just try a dozen or so different types and see what happens.

Thanks!

Bob

255. MAX712 NiMH Charger

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-14 05:00:13 UTC
From: David Snyder Hale <david@isi9.mtwilson.edu>
Message-ID: <93rbot$479$2@agate.berkeley.edu>
Source record: 55452

I'm trying to put together a fast NiMH charger using the MAX712 controller, pretty much following the Maxim data sheet.

The charger works in trickle mode only, and will not fast-charge. I can't figure out why, but I'm pretty sure that I've double-checked the wiring carefully.

I have a couple of suspects: according to Table 4 of the MAX712/MAX713 data sheet, "trickle-to-fast transition" is inhibited if either HOT* or COLD* is true. Also, it seems that (this is unclear) possibly unless GND < BATT-, it may not fast charge.

Well, for one, it seems that BATT- is always equal to GND.

As for the hot/cold issue, according to the data sheet they have THI (temp HI setpoint) tied to V+ (which is 5V) but in the characteristics table they say that the max input range for THI is 2V. Not sure if this could cause the problem.

Does anyone have any experience and/or suggestions with using the MAX712?

For what it's worth, I am using a pack of 10 NiMH AA cells, so PGM0=Ref and PGM1=nc. PGM2=PGM3=Ref. R(sense) = 0.2 ohm.

Thanks!

This is discussed in the 1957 ARRL Handbook and at the time P & H sold the modified tubes. An 807 and a 1625 are identical except for heater ratings and a different base.

Some manufacturers brought the lead to the beam forming plates out the bottom of the glass envelope where it was connected to the cathode internal to the base of the tube. In these tubes, you can unsolder the base and break this connection. For cathode driven use, the beam forming plate needs to be connected to the screen.

Other manufacturers did not bring the lead to the beam forming plates out of the envelope. It is internally connected to the cathode. These tubes, naturally, cannot be modified (unless you are a good glassblower with a multikilobuck vacuum system).

You may be able to visually see the internal connection with the latter brand of tubes.
If you do unsolder the base, be careful about cracking the glass since the base is glued to the glass envelope. Fortunately the glue is brittle and it can usually be removed from the glass rather easily. After you do the surgery, epoxy or cyanoacrylate glue can be used to glue the base back on before soldering. It helps to clean out the old base pins thoroughly as well as to use sandpaper to polish the pins. Tinning the base pins and the leads before final soldering is a good idea.

The 1957 Handbook discussed the entire amplifier design and gave the needed operating and bias voltages.

Fine-tuning between the synthesiser steps is sometimes achieved with a
DAC.

You might try making yourself some letterhead, and requesting engineering samples for evaluation for your new product. If the chip seems meets your needs, you _might_ need 20,000 or so for the production run.

>(any of these would suffice) :

Do you need a divide by 64/256 switchable or would one or the other do?
Also, are these for home projects? Novatech has a pile of old (now
obsolete) equivalent to the SAB1165. The actual part is the U264B from
Telefunken and is /64.

These are spec'd only to 1GHz, but they can be pushed. I am sure I
have a few-- maybe ten or so of faster /64.

264. Design help neede on RF AMP

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-14 18:11:17 UTC
From: szinn6_SKI@home.net
Message-ID: <3a61e82b.1695804@news>
Source record: 55461

I have built an RF Class C RF amp using a 2E26.
The speciifics are:
freq: 160 mtrs
Ep = 400 V Ip=50ma
Eg = -80 volt Ig= 2.5 ma

Input: Tuned LC cap feed into grip. Bias through RFC to grid.
Output: Shunt feed parallel LC coupled to a tuned link into 50
resistave load
Grid Bias: fixed supply

According to the RCA tube manual, with this congiguration I should get
typical usable output of 13 watts. However all I can seem to get is 6
watts into the load. The tunning seems to be working properly. I
have changed the tank LC and output coupling many times. No matter
what I do, I always get about 25-30% effeciency.

Looking at the grid with a scope, I can see the grid signal voltage
from ~ -80 volts going to +40volts. When the signal is removed, the
plate current goes to 0 ma. Which I assume is class C.

QUESTION: Any suggestions of what to try to get closser to the
specified output.

Any suggestion would be gratefully appreciated!
Thanks WA9WAS

==========
In order to operate in Class C the grid voltage is to be smaller than the cut-off voltage.
To find this cut-off voltage , reduce the grid voltage until the anode current is ZERO.
This is below -80 V in your case. Suppose you find the cut-off voltage at -85V.
The operating voltage for Class C operation will be somewhere in the -95 V region.

If you now apply RF drive ,the max permissible amplitude of the drive is 95+X where X is the positive grid voltage whereby the anode current is the rated maximum (in your case 50mA)

It means the effective drive voltage resulting in I(anode) = 50mA is 0.707* (95+X).

Have a look in any handbook describing valve operation and look for the Ig / Ia characteristic for Class C ; all the above will then be self-explanatory.

Hope this helps Good Luck

73 Frank gm0csz.kn6wh@ukrs.org

267. Re: Design help neede on RF AMP

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-14 19:58:36 UTC
From: Charles Reichert <kd9jq@mc.net>
Message-ID: <3A6204EC.6D81770@mc.net>
Source record: 55463

From an old RCA Transmitting Manual 10/62
pg 101 typical values

for CCS @ 125Mhz are:

Ep = +400V
Egrid2 = +190V from 19K series resistor
Eg = -30V from 10K series resistor
Vp RF driving = 40V
Pdrive = .12W

Plate current = 75mA
Screen current = 11mA
Grid current = ~3mA
Pout = 20W Peak

For ICAS service @ 160Mhz

Ep = +300V
Egrid2 = +170V from 21.5K series resistor
Eg = -75V from 30K series resistor
Vp RF driving = 85V
Pdrive = 1.5W

Plate current = 75mA
Screen current = 6mA
Grid current = ~2.5mA
Pout = 13W Peak

Now for 160Meters you may have to worry about
parasitic oscillations. Personally at 160 Meters
I wouldn't use a shunt LC with inductive coupling
because of difficulty in setting the load correctly.

Hope this helps some.

From the books I have the grid voltage seems to be about 2 times what it should be. You did not mention the voltage at the screen grid. Think it should be around 180 volts. You may have it so far into class C that it takes more drive.

1.. generally takes out noise from sparks from brushes on alt or generator
and
spark plugs..
2 keeps rf out of filaments in pwr finals
3 general purpose rf inductor
4 i don't know but would guess it has to be low "q" and therefor would have
hi dc res and wider frequ response than a narrow band on e with high q..

I've built one that covers from ~35MHz to ~85MHz so I imagine that it would be even easier in the range that you mentioned.
One thing I've noticed though is that the output waveform at the lower end of the range is awful. Something to do with the varacter characteristic I think. I'm now looking at multiple VCOs to get a clean output for the entire range. Might not be a problem with the frequency range you're talking about though.

Regards
Murray - VK6HL

Rob,

Hash chokes are designed to eliminate "hash" from going to or coming from low voltage lines, like 12 vdc. They are used in automotive cases and home cases where switching power supplies are used.

Current RF choke is designed to handle say half to more than an amp or so in high voltage applications for RF amplifiers. Current ratings are even much higher for solid state designs.

An RF choke is similar to above but is usually in the 50-200 ma range.

Wide band choke is designed to handle a broad range of RF frequencies. A grid choke on a grounded grid amplifier is an example.

73s,

Evan

Hi there.

HOW ABOUT a LINK to the NEW CRYSTALS swapping BBS?

There is a NEW Crystal Exchange Message Board (free) on the
web at:

http://senac.com/boards/880/

There you can post sale & want ads and find radio crystals for sale
by others!

Sell your excess crystals there!!

The previous old message board was being ruined by Taiwanese
infiltrators that ruined it with off-topic SPAM ads. This one is
secure.

The above is all hobbyist and non-commercial. OK, the BBS has
sponsor ads, that is how we get it free.

I have concentrated all of my HAM LINKS
efforts over the past few years to editing the Open Directory
system, and I am the editor for all of the Ham Radio
BOATANCHORS links on there.

I like the robot that automatically removes any bad links for me!

Never any 404 errors!!

We have a broad variety of specialty links to over 700 sites
(arranged by category) of interest to hams who enjoy antique rigs.

Please also link to:

http://dmoz.org/Recreation/Amateur_Radio/Boatanchors/

Source record: 55478

This morning I was playing with the DX-375 I bought on clearance a week or two ago, and ran into a mix I can't figure out. I'm picking up both 1110 KHz and 1160 KHz on 1360 KHz... IF the "DX" switch is not in the "DX" position. Funny thing about this radio is that SW and FM are more sensitive in the "DX" position, while AM radio is *less* sensitive (though not by a lot, certainly not enough to explain the very strong mix disappearing).

I looked for other images, thinking in terms of synthesizer spurs, but there was nothing else receivable that wasn't also receivable on another radio.

Source record: 55481

Thanks to all those who offered assistance. My main problem was, and I'm ashamed to admit it! Was I was measuring 'Ip' in the cathode instead of the plate! DOOH At such low plate current levels, the non RF producing G2 current was calculated as being part of the Ip. This caused me to tune the amp up at much to low of current. Therefore the low effeciency. The grid drive was suffecient to overcome the -120v Eg1 and drive the grid to +40 volts. That was the major mistake. I also discovered the meter I was using had a different internal R from what was advertised. This caused the Ip reading to indicate too high, Also causeing the amp to be tuned at too low of current. With these fixed, the amp is running at 76% effeciency, the target was 75%.

I wish to thank those whom offered assistance. 73 & DX

Hello--
If you're close to either station, chances are the receiver's front end may be saturating in response to the "DX" switch setting.

The signal on 1360 KHz is probably due to a mixer product of the form:

F = n*f1 - m*f2 or F = n*f1 + m*f2 - p*f1

...where F = 1360 KHz, f1 = 1110 KHz, f2 = 1160 KHz

...and m, n and p are integers to be calculated by the reader<g>.

I dimly recall reading about an online mixer spurious-product calculator offered by a mixer manufacturer-- possibly Minicircuits. Help, anyone?

You can also try a search on www.google.com.

Try disconnecting or drastically shortening the receiver's external antenna to see if the spurious response goes away.

73--

Message-ID: <9429qg$8sj$1@nnrp1.deja.com>
Source record: 55489

My $0.02, which will echo some of what's already been posted:

It's a tradeoff between noise and bandwidth. You can make a vco that covers well over an octave in one range, if you want, but for example, if you tune 50MHz with a 5 volt control voltage swing, that's 10MHz/volt, assuming it's linear. If your control voltage has, say, 10 microvolts of noise on it (which is reasonably quiet), that represents 100Hz of FM. That might not be acceptable. And that doesn't even consider what noise sources might be in the oscillator itself. I've designed VCOs with crystals and a tuning range of around 10kHz so I could have a locked ADC clock with very low jitter. I was just looking at the HP/Agilent 10811 10MHz crystal reference oscillator specs and noted that it recommended using a low-noise control voltage for its VCO input, which swings the osc only 1Hz, to keep phase noise low!

For an example of how it's done in a commercial product, you should be able to find the schematic of the oscillator in the HP/Agilent 8662 synthesized source, which is noted for low noise. I've seen the schematic published in an aritcle on low-phase-noise VCOs by Ulrich Rohde. Perhaps it's this one: Rohde, Ulrich L, "Designing Low-Phase-Noise Oscillators," QEX, ARRL Experimenter's Exchange, October 1994. It will be very hard to find a schematic with all the details, but the essence is to use (PIN) diodes to switch inductors and/or capacitors to make one oscillator cover a moderately wide range. Note that you can also use a transmission line or helical inductor, and switch capacitive loads onto it. You MAY find it advantageous to build a VCO at higher frequency and either mix or divide down. If you build a VCO around a very high Q tank, you can get lower noise, and you can get higher Q in a small volume at higher frequencies, assuming you're using an LC, line or cavity tank.

I've kind of jumped into the deep end with respect to phase noise here, but most likely it is important. A web search or two will surely turn up lots more info.

Cheers,
Tom

As far as the active components go, I would expect ones used in hearing aids to be highly integrated. A lot of semiconductors are available unpackaged...probably almost all are, if you are willing to buy enough of them to capture the manufacturer's interest (and then deal with wirebonding). The transducers are likely "proprietary". You might try contacting hearing aid manufacturers. I recently heard about "disposable" hearing aids, and that might be a source of parts for 'sperimenting with if that's all you're looking for, though dismantling them without destroying things inside might be a bit of a challenge.

A few years ago, I'd have called sot23 and sc90 transistors (and op amps), and 0402 R's and C's, "ultra-miniature" but now they are almost mainstream. I assume you want things smaller than that.

Cheers,
Tom

Hey, nothing's too deep! It's for a general-coverage HF DC
receiver (the short of it here is that it's using a DSP
backend to do all the demodulation), so low noise == good.

> 1994.

Rohde talks a little about the 8662A in
http://www.amazon.com/exec/obidos/ASIN/0471520195, comparing its VCO
topology to a couple of different R&S models. I'd order it from
someplace besides Amazon, though -- their shipping time for less-popular
books has grown exponentially over the past year or so.

Also, anyone who's interested in the 8662 or low-noise signal sources in
general, and who has access to back issues of "HP Journal," should track
down the issue from the auction at
http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=1203599951. I
just bought this one, and it's worth every penny.

Of course, if I could just get the ebay crack monkey off my back I could
afford a real, in-the-flesh 8662A to play with....

298. Dynamic Range

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-16 22:37:04 UTC
From: ralph <crlane@erols.com>
Message-ID: <3A64CD10.12E7440C@erols.com>
Source record: 55493

I have been reading about receiver dynamic range where some writers are saying that crystal filters are subject to signal overload (also mechanical filters). Does anyone have any experience or any reference to literature about this? There has been a lot of attention paid to developing high intercept point mixers (+40 to 50 dbm input intercept), thus it would seem the if crystal filters will be generating a lot of distortion products.
Any thoughts about this?

Ralph

Ralph,

I don't know about literature references, but filters do have IMD just like everything else. We used to do two tone (third order) testing on crystal filters as part of the normal production line testing. It's been quite a while since I was involved, but numbers in the +50 dbm intercept point (80 db below two +10 dbm tones) sound about right for the stuff we made back then.

From: Charlie <null@null.null>
Message-ID: <B68A4C4B.38CE%null@null.null>
Source record: 55397

Hello,

I am a high school student with a tech class ham ticket that I got 4 years ago, and I don't remember much about electronics. I am just getting back into the hobby. However, I wish to build a lower power CW transmitter that TX on the AM broadcast band with very, very low power -- 100 mW or so for a school project. Just enough to transmit to a standard AM RX a couple of feet away. I checked out a bunch of books about electronics from the library, so really all I need is a list of parts and instructions on how to put the unit together. I have a CW st. key that i can use. Thank you!

P.S. I have seen many kits, etc for FM phone and AM phone that TX on the broadcast bands, but nothing for CW. Thank you.

>Well, that's what it remembered too until I looked in my 1962 ARRL handbook. It
>shows two different pinouts, one (5AW) for the 807 and another (5AZ) for the
>1625. The 807 doesn't show a suppressor grid (beam former) as does the 1625.

That's a drafting error I had them correct in very-much-later
Handbooks. The 807 and 1625 are electrically identical except for
heater voltage and basing.

One postwar divergence between 807s and 1625s is that some
manufacturers started making 807s without the ceramic insulation and
stem shield that had been standard in both types. The result is a tube
that's potentially less stable for RF purposes.

This amplifier was described in E. L. Hoover, W9SAR, and R. L. Peck,
W9MOW, "A 200-Watt Grounded-Grid Linear Amplifier," QST, June 1955,
pages 21-22, 128. (You can infer from the authors' names where that
company name came from.) Yes, the tubes are operated grounded-grid,
without bias, and at the plate voltage used idle at 10 mA each. That
the circuit includes no means of checking the tubes' grid current,
either individually or collectively, is troubling, as a later QST
article (V. S. Campbell and W. S. Skeen, "Grounded Screen-Grid
Operation for Tetrodes," QST, November 1959, pages 37-39) detailed;
its deck reads: "A tetrode with control grid and screen tied together
to form a high-mu triode for a grounded-grid circuit makes a very
simple arrangement. However, this type of operation invariably results
in excessive control-grid dissipation. This article shows a simple
method of avoiding this difficulty." The absence of grid-current
monitoring means you'll have a hard time determining whether you're
overdriving the tubes without spectral or oscilloscope analysis.

As other respondents have written, the reason the 1625s needed to be
modified was that a beam tube's beam-forming plates, if hardwired to
its cathode, provide a built-in cathode-to-plate capacitance that
would bypass any screening achieved by the grids and require
neutralization for dependable stability. This wouldn't apply to the
837, which is a true pentode (with a separate, true suppressor grid)
and not a beam power tube; but the 837 has a considerably lower
power-handling capability than the 807/1625.

Hi

I am fairly new at homebrewing and was wondering how most of you order your parts. Does anyone have a good supplier I can just email a list of parts pay for it, and have it shipped? Much of the parts I have are from desoldering misc junk I find here there and everywhere, but some of these new projects I am looking at have some hard to stumble apon stuff. Most of it, from what I ahve noticed is available from radio shack, but they are so expensive with everything, I am sure I can do much better.

Thanks
John

You never seem to ever have all the parts you need for a project.

One place to check out would be Dan's Small Parts. He's a single
person operation, and he carries parts that radio experimenters
would be interested in. It's not a greater place to buy a
wide selection of parts, and there are some radio-related
parts that I wish he'd carried, but you can get common transistors
and variable capacitors and toroids and other common parts from
one sourece. You can see what he carries at:
http://www.fix.net/dans.html

Possibly the simplest CW transmitter for the AM band would be another receiver. An ordinary AM receiver has a local oscillator that runs 455Khz above the frequency indicated on the dial. That can usually be picked up by a nearby receiver. If necessary, you could wrap a few turns of wire around the local oscillator coil in your "transmitter" and feed this to a small antenna.

Your problem will be receiving CW on an ordinary AM receiver. You need a BFO to make the signal audible, or some regeneration in the IF. If you are using a communications receiver tuned to the AM broadcast band, then you have this, but if not, you'll have to improvise.

Doug Moore KB9TMY

312. Re: Low Power Homebrew CW TX

Newsgroup: rec.radio.amateur.homebrew

Message-ID: <9447a0$bq4$1@slb3.atl.mindspring.net>
Source record: 55409

I have not seen any kits to use in sending CW in the AM broadcast band.
Besides, the broadcast band recievers don't have any BFO signals so they'd
have to be modified to receive CW.

==========

Actually, if he can find a kit for phone transmission on the AM band, I'd
suggest feeding an audio oscillator into the mic input and keying the audio
oscillator.

This would allow using an easy to get kit, and remove any need to change
the reciever... While still effectively transmitting CW for all practical
purposes.

Source record: 55414

Gday all
I battled with this device for a month before I gave up and went on
holiday..
Good to see I am not the only one having problems.
I could not get any sense out of the chip in serial mode beyond
getting the IOUD pulses at 1/128 main clock after a master reset.
I tried gating the main clock after reset (the revised data sheet says
the reset should be held high fr 10 clock pulses) to allow the entry
of a 4 byte serial word to address 7 before the chip internally
updated. This had no effect. I could not seem to get any serial data
into the chip - I couldnt change PLL status or current consumption by
switching on/off any sections. I even tried parallel loading one byte
to the register controlling IOUD by controlling serial/parallel mode
and hardwiring the address pins at startup - still couldnt turn off
the IOUD pulses. I havent managed to getan output from the chip or
change the DC level of the DACs by loading data into the multipliers.
I tried delays and multiple initializations to no avail

HAS ANYONE GOT WORKING CODE or pseudocode for initializing the device
in serial mode they are willing to share??
It looks as though I will have to build another board with parallel
mode.... :(

If you are interested in the power at a particular point, then that is where the meter should be placed, unless the line attenuation is accurately known.

If you are trying to infer SWR from power ratios then the placement should not matter, except that line attenuation will make the ratio better at the sending end than it is at the load end.

There are no 'magic' lengths.

Wes
I beg to differ. Bwlow 100mhz line length is not that critical BUT at freq above 100mhz it becomes very critical to measure both fwd power and ref power. See last page of Bird 43 manual.
I use one at 432mhz and trust me I can make that bird 43 read all over the place just by changing the length of feed to it from the transmitter. Same as you can make a mis-matched ant look good to the rig by varying the feed line length.
We are talking about sine wave's here, and where you look on the sine wave (feed line length to bird 43) will either show the true fwd/ref power or much less of both.

True, they're not always cheap. But if we want to buy
products in onesies and twosies, in an industry that
is geared almost entirely for OEMs, we must pay the price.

I often seem to find myself in towns with good local
electronics places. Here in Vancouver it's RP. In Seattle
and Portland it's Radar. In Toronto it's Active Surplus
and Sayal. And so on...

Another good reference is the components suppliers list
in the ARRL Handbook.

Well, CW is just a carrier. The AM broadcast band is kinda nicely centered around 1MHz. There happen to be loads of cheap 1MHz crystal controlled oscillators out there for use in digital electronics, just apply 5V DC and they oscillate at 1MHz (or whatever the crystal freq is). These things are typically a small rectangular metal can, about 1/4 x 1/2 inch, with 4 pins. One pin is +5V, one is the oscillator output, and the other 2 are ground.

So, just get 5V, a switch (or, better, a key), and hook a piece of wire to the output pin for an antenna. Presto, you now have a simple CW transmitter! Of course, the output is actually a square wave, so there's lots of harmonics. And, the hunk of wire is likely a lousy antenna (of course, you could design a better one of those too). Receiving will be easy, but unimpressive (i.e., it won't make the nice "tone" usually associated with CW/code), but you will likely be able to tell that it's there.

I'm sorry Bob, but clearly you don't understand what both Bird and I are saying.

With respect to what Bird is saying: Assume that you have a mismatched line and you start by installing the Bird and making adjustments to the transmitter to maximize the foward power into the line. If you then remove the Bird, you effectively shorten the line by 4 inches. If the four inches is a significant fraction of a wavelength, which it will be at higher frequencies, then the transmitter will see a different load and perform differently. Bird touches on this subject in the second paragraph of section 7.

The forward and reflected powers will be different, however, their ratio will be the same. If you are using the ratios to compute SWR at that point, then your computation is valid, whether or not the Bird is in the line.

If you are getting different (SWR) answers by changing the line length between the transmitter and the Bird, then you have problems with common mode currents on the *outside* of the transmission line. The SWR on the line is *not* affected by anything going on in the transmitter, it is set by the degree of mismatch between the load and the line. You might indeed be seeing differences in power, but the ratio between forward and reflected should not change.

What I was saying is that the only effect that moving the position of the meter has occurs when the line loss is significant. For example, assume that the line attenuation is 3 dB, the transmitter output is 100 W and the load SWR is 3:1.

If the meter is placed at the load the forward power will read 50 W and the reflected power will be 12.5 W. You can verify that this is 3:1 by looking at the chart in the appendix of the Bird handbook, if you don't believe me.

Now if the meter is moved to the input of the line, the forward reading is the full 100 W and the reflected reading is 6.25 W. The new power ratio is 16 which is 1.67:1 SWR, which can also be approximated from the chart.

Please note that this difference is due only to the line attenuation; a magic length and/or the characteristics of the transmitter have nothing whatsoever to do with it.

From: Les Rayburn <les@highnoonfilm.com>
Message-ID: <t6bnl3nl607ue2@corp.supernews.com>
Source record: 55421

I'm hoping that I can find someone willing to help out a "soldering challenged" ham. I'd like to pay someone to build a simple, crystal controlled 160 Meter CW QRP transmitter.

Nearly any design should work. I'd like for it to operate at 1.999.91khz in CW mode only. Output power should be 1 watt or less. Happy to supply mone for parts and labor. No case needed, but suggestions for connectors would be welcome.

The only other catch is that I'd like to get it by the end of February. If you're
interested, please contact me by e-mail. Thanks!

Dear fellow hams

A couple of weeks ago, there was an item on this newsgroup about someone looking for a voicekeyer. I then said I was thinking of a design for using the PC's soundcard and printerport (LPT) to implement a voicekeyer.

Several OM asked me to publish all this as freeware, so apparently there was some minor interest in this small homebrew project.
Well, it's done and if anyone thinks he can use it, feel free to download it. I designed the hardware for my TS-850, so using it on other rigs means you have to do some research yourself.

I think the hard- and software speak for themselves, you should, however, have your own software to record wav-files.

I'll try to answer all questions. Let me know what you think of it, and if I should change or add some functionalities.

Read all about it in the homebrewsection of my page:
www.qsl.net/on4cln/

Hi Wes;
I agree 100% with what you said about SWR. What I was referring to by the different readings
with the bird 43 with different feed lengths, was the Power Measurement. Since I thought the person asking the original question was asking about using a bird 43 to measure power.In that case the feed line length is very important if the freq is high enough. As far as swr goes like you said the ratio will stay the same independent of feed line length to the meter (correct also on the slight diff due to feed line loss not to mention that the fwd power also contains the ref power).
In my case I use Bird 43 to measure mainly my power out to be legal on 144 and 432 mhz. That is why I was talking about how important it is the have to correct (I believe it is odd multiples of 1/4 wave length) between the transmitter and the Bird.
Sounds like we are all correct Wes, just talking about different aspects pwr vs swr in using the bird.
You are also correct that removing the bird will shorten the feed length by about 4" and thus the impediance can be affected as perceived by the transmitter(due to the diff new feed length). Wheather the 4" will really matter or not mainly depends of the freq. At 75 meters who cares but at 70cm that is almost 1/4 wave and for sure will change things hi hi.

This is a hard chip to figure out, but it does everything in the data sheet
the way they say it does (with a few timing errors and some typos). It
requires sitting down with a pencil and mapping out everything step by step
in exactly the right order. Trust me it works. Unfortunately, I can't
post the code. I am pretty proud of it, but Novatech would be upset.

A month is not nearly enough time.

Good luck.

Steve.

Bob,

Just so I better understand just what you are saying here, do you see a significant difference in indicated power if your load is matched 1:1, in you 440MHz system, as you change line length? Which line lenght, if so? (That is, the line from amp to meter or meter to load?) Or do you see that effect only when there is a mismatched load? Do you see it operating into a dummy load, or only into an antenna system?

Cheers,
Tom

Might check the Handbook, I recall a synchronous and
quasi-synchronous AM detector mentioned in there.

It was a simple question, if your not intelligent enough to acknowledge that a radar detector is simply a Ultra Wideband receiver that can function up to many Gigahertz then you are a fool.

I asked here because 'some' amateur radio homebrewers have done such circuits before. I was looking for one of them on this list.

If you have no answer, or nothing useful to add, dont post a reply. Thats a waste of my time, and yours.

Hi, Bob,

Take a look below at what the original question was and you will see:

"I think I read sometime long ago, that the length of the measuring cables
connected to the SWR-meter was rather critical."

Because the post refers to a 'SWR meter' I addressed that aspect of its use.

> In my case I use Bird 43 to measure mainly my power out to be legal on

>things hi hi.

Well, it the load is matched to the line (and the line Zo is 50) then there
shouldn't be any change.

I am still disturbed by your statement that you get readings "all over the
place" when you move the instrument around. If you mean that there is a
difference between the transmitter end and the antenna end then okay. But if
you are just adding a few feet and seeing an effect then something is seriously
wrong.

I see you're using a 4CX1600 at 432. That's quite a bit above its full power
frequency spec. What kind of efficiency are you getting and are you sure you
don't have a harmonic or spur problem?

I too run an 8877 on two meters. Was thinking about asking for a sked sometime when I get an antenna back in the air, but I already have your grid :)

73,

Wes, N7WS DM42jh

Hi,

The part works fine in serial mode. It takes some time to figure out some of what they are trying to tell you in the data sheet, but it does work. The code I have is in PIC assembler and it's pretty long. Much more than would be reasonable in a news group. A simple approach to getting it running:

1) Check the mode select pins to be sure you are in serial mode (I wasn't ....)
2) Bring the chip up with the clock running. Forget about trying to init it first.
3) Reset the chip before you start
4) Do an i/o reset before each serial transfer
5) Just take it up to the point that you shut off the IOUD when you are debugging the serial i/o. Anything more than this will just confuse the issue.

Once you get the serial running then my comments to Craig below may apply.

Most of us have gotten the part running, but it isn't an easy part. There's just to much going on inside the darn thing.

Hope this helps.

Even with an 'ideal' detector, the audio will never be very 'hi-fi' with a 7 KHz IF bandwidth. At most you'd get only 3.5 KHz audio bandwidth, and probably less depending on the passband shape of the IF filter. The best you can hope for is to minimize distortion in your detector, but distortion is ultimately also affected by the IF filter because it can skew the phase of upper and lower sidebands relative to the carrier.
If you're interested in listening to commercial AM-band stations, there's also a fundamental limitation imposed by the station itself. At the low end of the AM band, the bandwidth of the transmitting antenna is often only several KHz. This also limits the high frequency response of the audio.

There's a little bit more to it than that. The traditional
hand-held radar gun operates at about 10.7 GHz, while other
technologies (photo radar, GATSO, etc.) operate around 24
and 35 GHz. Then there's the laser stuff...

To detect any one of these is doable; detecting all four
is a fairly tall order. As you mentioned, you don't even
know which frequencies you're looking for, which makes
matters more complicated.

Personally, I've had two speeding tickets. In one case, it
was X band radar, coming around a corner. In the other case,
the cop pulled up behind me and clocked my speed directly.
A radar detector wouldn't have helped much on either.

This isn't "schematic" stuff - it's waveguide and microstripline.

Matt, I note that all you have ever asked in this newsgroup
are requests for schematics that are either unrealistic, or are
well-covered in standard references. Perhaps you should give
some thought to what you ask for before you bitch about
the responses you get.

Source record: 55436

Unless the antenna is not well balanced and you have RF currents flowing on the outside of the shield, the length of line between the transmitter and the wattmeter shouldn't make any difference *except* that forward power will drop as you move farther away from the transmitter due to the increased loss in the line. Any changes in forward and reflected power as you move the position of the meter is caused only by the change in loss in the line, regardless of the SWR. It should not be necessary to use multiples of 1/2 wavelength to get an accurate power reading.

Hi Wes;

First off its a 4cx1600U coaxial base with cutoff freq of 1000 mhz.
Power out
runs about 2kw at 55% eff on 432. You must be thinking of a 4cx1600b.
And yes even with the bird on a 50 ohm dummy load varying the feed line
length into the bird 43
gives different readings for sure. Example with just the exciter putting
out 42 watts by varying the feed length INTO the bird I can get readings
all the way down to about 20 watts with same 42 watts out of rig.
I went from normal input feed length (shows 42 watts) to adding about
6-7 feet more to input feed. Tried different pieces (lengths) of coax.
Been sitting here playing with it on the dummy load. Not using amp, just
ft-847. I have seen the same thing on 2m with an IC-746 setup.
I know bird says it is traveling wave type meter but I have 3 birds
here and a coaxial dynamics
and 2 diff vhf/uhf rigs and have seen the same thing on them all. Try it
and let me know if you can see a difference.
RR on the original post on swr. Sorry I didn't keep up better on the
original post. This is turning into an interesting discussion.
Thought about editing some of the below off but might help to leave it
so folks will know what this is all about hi hi.

Thanks to everyone for a great thread and some wonderful memories!
I built an amp with grounded grid 1625's as my first ever homebrew amp.
This would have been in roughly 1964 or 65 at the latest.
It used 6 in parallel. I certainly do remember sawing those rectangular
windows into the sides of the phenolic tube bases. It was possible to
place the opening such that you could perform the surgery without
completely removing the base from the envelope. My first amp was of
dubious utility on 20 meters but did give me some good early
experience. :o) I eventually traded that HB amp for another local
hams HB pair of 4-400A's. He was getting married and moving into an
apartment or some such, and wanted to downsize. I definitely got the
better part of that deal. :o) 73, David K3KY

A radar detector is hardly an "ultra wideband receiver".

CQ Magazine ran an article about building a radar detector in
1957 or 58. It wasn't much more than an antenna, a diode and
an audio amplifier. Not very sensitive, though it was my impression
that that was what was inside early radar detectors.

When Gunnplexers started being popular in ham circles, there was
another wave or "radar detectors" in 73 Magazine, about 1978 or so.
If I recall, they used the same sort of antenna that Gunnplexers
were using, ie a mechanical matter, and modulated the detector diode
with an audio tone, and again fed the result into an audio amplifier.
Apparently, it was better than the original scheme, though I have
no idea what the commercial detectors were using by that time.

But at some point, the commericial radar detectors dropped the
idea of such simple. They went to a superhet design, under the
idea of longer range. A similar type of antenna, but a local oscillator
that mixes with the incoming signal to move it down to a lower frequency
for handling it. I forget the exact scheme used after detection.
I never saw a construction article about this, but in the mid to late
80's, 73 Magazine ran an article about converting such a radar detector
to something useful to hams.

Radar is a wideband modulation, but you aren't dealing with a wide
slice of the spectrum at a time. You have to specifically set out
to handle a given type of radar.

Now, it occurs to me that perhaps we have misinterpreted your question,
as often happens when the original question is vague. We all seem
to be thinking you want a unit to detect police speed radar. Perhaps
it is some other kind of radar you specifically want to detect,
or maybe you want some means of measuring the output power of some radar
unit. Or, considering that microwave ovens were once referred to
as "radar ranges", maybe that was a slogan for one manufacturer,
perhaps what you want is a detector to see if your microwave oven
is leaking microwave.

Sometimes it helps to ask a question properly, with enough detail,
so nobody's time is wasted.

It is safe to assume your Kenwood receiver is already equipped with a detector capable of extracting the best possible performance commensurate with the RF and IF receiver stages when connected to an external loudspeaker.

If you wan't an even better performance there is no alternative but to obtain another complete receiver of even Higher-Fi, at every stage from aerial to loudspeaker.

In principle, the forward and reflected power meter always gives the correct answers. It is the responsibility of the user to decide what happens when the input and output line lengths and impedances change, or the meter (and its effects on the system)is just removed from the system.

There's a small program available from my website below which models behaviour of ALL types of fwd/ref power and swr meter.

Download in a few seconds program SWRMETER. Not zipped up. Run immediately. Look for divergencies from expected readings in the presence of different source and load impedances.

In practice, departures from licensed power levels, either up or down, either actual or imagined, are of little significance. If the wattmeter indicates the power into the antenna is in the right street then there's nothing to worry about. If you just show a visiting inspector your Bird wattmeter he will probably go away without any further questions. He probably doesn't have one himself.

Some years ago I was given what I was assured was a well used but still operational Gonset Communicator, since then it has been stowed away in the bottom of my junk box.

As I'm more interested in building/tinkering than operating I can't see me ever wanting to put it back on air however, before I do something drastic, I would be grateful if could someone tell me if this equipment has any historic value ?? Looking at the manual it would appear to be an original & definitely not the MkII version (no slide switches under the Rx tuning dial) & the Xtal that came with it is an 8.000Mhz FT243 marked (but marked 8.070Mhz).

There is no serial number on the equipment & I've no idea of date of manufacture but suspect late '50s, early '60s. If it is of some historic significance can anyone suggest who would be interested in it as I might be prepared to give it away to a good home rather than see it broken down for spare parts ?

Source record: 55445

Hi guys,
thanks a lot for the interest in my question!
Maybe I should specify what it is I am trying to do here.
I have noticed that when changing the length of the connection cable between the
coax coming down from the antenna and the Bird 43 I get different values on the reflected power.
I am talking about 144 MHz signals.
The reason I connect an extra cable between antenna coax and meter is that it is more convenient to do
it this way due to small space where the rig is at. Normally the meter is not connected to the system.
So I figured that if this extra connection cable was a half wavelength long, it wouldn't change anything, as a
half wave length of a cable is "transparent" if you know what I mean. The impedance is the same on either side of the cable at that specific frequency.
Of course if the conditions were ideal, a 50 ohm load, 50 ohm line/connectors, the length of the extra cable wouldn't matter. But suppose there's something wrong with the antenna or perhaps there is water in the coaxcable, then the load impedance as seen by the transmitter wouldn't be 50 ohms and that would create standing waves on the line.
So by inserting an unspecified length of cable between antenna cable and Bird I could be fooled to think that
I have a perfect system because I could be "lucky" enough to hit a spot on the line where the reflected power is at a minimum. Remember we have standing waves now.
But by making the extra cable a half wave length long I wouldn't change anything and so get a correct reading on the meter.
That is the idea I was trying to get confirmed here. Please correct me if I am wrong.

Built it. It works, but the PLL will require some tinkering. The bottom line is very simple: It produces nice audio on groundwave signals. Don't expect it to hold through a selective fade, however.

RIght you are. Forgot about the 'U" version. That's excellent efficiency on
432. I'm thinking about build something more compact than the W6PO two meter
amp that I now have. All that pipe (silver-plated no less) and still not much
better than 50-55% eff.

Since you have multiple meters, I assume you are leaving one connected to the
transmitter through a fixed length of cable as a 'reference' and varying the
line length between that one and a second one. True?

If that is the case and the first one always shows 42 watts, then at the moment,
I'm stumped. If this is not what you are doing, then I encourage you to try it.

Two issues: First, with a good envelope detector, he can achieve a
decent response (6 kHz, realistically) if he tunes off to one sideband
or the other.

Second, phase distortion depends on how many poles the filter has, how
high the Q of each pole is, and how tight the coupling between those
poles are.

It's true, many filters do have excessive phase distortion, but
without knowing what filter he's talking about, I wouldn't jump to
conclusions.

True, but there's no point in making things worse by using a poor
detector on it.

I've had a notion of building a decent Costas Loop detector for 455
kHz and for 70 MHz using good diode DBMs.

The usual gilbert cell mixer and LM386 combination just doesn't cut
it...

Ingvar:

Yes adding 1/2 wave length is correct to duplicate what what you would normally have
(reflected power without the bird in the line), to the line when using the bird 43. The impedance is 50 ohms every 1/2 wave length on a rf signal reflected. Adding the extra 1/2 wave length of cable will let the bird see exactly what your rig would see (without the bird being added). This does not mean you would be seeing necessarily the full reflected power unless your original cable was exactly an odd multiple of 1/4 wave to begin with. If your original cable was exactly an odd multiple of 1/4 wave to begin with, then adding exactly 1/2 wave length more will keep it an odd mutilple of 1/4 wave length.
This is the ideal situation. Of course if the antenna has swr and you are not sure of the length of the feed line to antenna, then adding the 1/2 wave length will let the bird see what your rig sees impedance wise and reflected power wise.
You are also correct in that standing waves (swr) at points on the feed line can read near zero. That occurs every EVEN multiple of a 1/4 wave (i.e.. every 1/2 wave length).
If you just want the bird to see what the rig is seeing then add the 1/2 wave length. If you want to know how much reflected power you really have (and your feed line is not cut to odd multiples of 1/4 wave to begin with) then just start adding random lengths to the feed line till you find the max power reading of swr. That should then be the odd multiple of the 1/4 wave I have been talking about.
If you draw a sine wave (1 cycle) you will see that the max Positive power occurs at 1/4 wave length, and the max Negative power occurs at 3/4 wave length.
Conversely, the minimum power occurs at zero and 1/2, and 1 wave length. Sorry for the long rambling reply, but this is easy to draw and explain but hard to do in just words hi hi.

Ingvar,

Consider the previous discussion. We have (generally) agreed that except for the effects on line attenuation, the SWR is everywhere the same on a length of line. Therefore, you cannot ever be *lucky* enough to pick a length that provides a match.

Think of it this way: Pick a point on the Smith chart for the load impedance. Let's just say the load is 100+j0 (SWR=2.0:1). Normalize that to 2+j0 and mark

it on the chart. Now add 1/4 wavelength of lossless 50 ohm cable.

The point now rotates toward the generator 180 degrees (twice the line length) to the point 0.5+j0. Unnormalizing this is 25+j0 which is still SWR=2.0:1. The same will be true at any intermediate point; we are after all just rotating around a 2:1 SWR circle.

Another example might show what I believe you were thinking. Let's use the same load impedance 100+j0 but normalize the chart to 70 ohm. The normalized load is now 1.429+j0. If we rotate this around the chart 180 degrees, we land on 0.7+j0. Unnormalizing we get 70 * 0.7 or 49+j0. This is very close to 50 and of course demonstrates the 1/4 wave impedance transformer. Had we selected the geometric mean of the two impedances to be matched (sqr(50 * 100)) for the transformer impedance, the result would have been exact.

So, the only way adding a random length of cable to your system can change the results is if the cable impedance is different from the system impedance. No need to worry about a particular length otherwise.

Bob;

Here is a quote right out of the bird 43 manual...

"What happens when the load is not well matched, like with an antenna
with a VSWR of 1.5 or 2.0?
Since the length of a line between a mismatched load and the source
trans-forms the impedance of
of the load as seen at the source, line length now becomes critical.
If the adjustment for maximum power transfer were made with the "43" in
place, removing it shortens the line by 4 inches, plus two connectors.
This still is no cause for concern at low frequences where 4 to 5 inches
is a small fraction of a wave length. At higher frequences (e.g. above
100 mhz) power output and frequency of the source may be affected.
It is a principle of transmisssion line theory, that the impedance is
identical on either side of 1/2 wavelength. In order to duplicate the
conditions in your transmission line with the "43" either in or out of
the line, it is necessary to insert or remove 1/2 wavelength."

This is right out of the bird 43 manual. The only way none of this
matters is IF your rig is exacly 50 ohms and your feed line is exactly
50 ohms and the antenna is tuned to exactly 50 ohms.
Then you would have no vswr in the first place. Like it said a low freq
it is not a problem due to the small portion of a wavelength at those
freq's.
At things like 2m it for sure matters, and at 432 and 1296 mhz just a
very few inches can make all the differences in the world on what you
would see.
It is not a matter of line loss but Standing Waves inside the feed
line. Like bird said even with a vswr of 1.5 it matters at 100 mhz and
up.

Dick,

The Gonset Communicators were the staple VHF rigs of the mid 50's and early 60's. Originally designed as emergency tranceivers for aircraft, the Amateur Radio models eventually outsold all the CAP models. I grew up in Southern California, and even visited the Gonset plant once when I was in High School. Our High School Radio Club used the 2m Gonsets during the football season to relay scores between schools. We'd set one up on the hill at Griffith Planetarium as a relay station. (There were outlets in the concrete wall around the planetarium where we got "free" power.)

I owned one of the 2m rigs for a while. About 1955, there was a guy who made knobs with a press fit collar that fit over the hex shafts on the Johnson variable capacitors that were used for tuning adjustments. These were so popular it was hard to find a Communicator without them. In the model III, Gonset included knobs for all adjustments.

The case was designed with dimensions to be complementary to the antenna connection at it's top. If you measured from the antenna connector around the case to a point on the opposite side, it was pretty close to 19", or about the length of a radial for a 2m ground plane. That's why they worked so well with just the whip on the top.

The rigs were also pretty versitile, available with power supplies that operated on either 6v, 12v, or 117V. The switch from AC to DC was made via a multi pin Jones plug on the back of the rig. An automobile battery would power the rig for 8 to 10 hours as I recall. (I believe there was even a switch on some models to turn off the dial lights to conserve power on receive.) I took my own Gonset on numerous camping trips. I even tried to use it on a bicycle once, but was not very successful because of having to reach behind me for the transmit switch.

So yes, the Gonset is a piece of history. Maybe not so much in the UK, but certainly here in the US. Perhaps it could be likened to the Wireless Set 19 of the US, though made much later and for a different purpose.

Thanks for your comments again - forgive my persistence but I dont
usually let a project defeat me (this might be the first!)
I may have to do another proto board and redesign the hardware with
the parallel option also.
After a few weeks holiday I might see where my error is (no doubt
there is one!)
Is the chip particularly static sensitive?
I fear I may damaged it with all the mods and fiddling around

Wes;

Think about this. Say you have ant antenna that is 100 ohms impedance
with 50 ohm feed line and a 50 ohm rig.

BIRD SAYS WITH SWR

"It is a principle of transmisssion line theory, that the
impedance is identical on either side of 1/2 wavelength."

That tell me the feed line will have an impedance from 100 ohms (the
antenna 100 ohms above) all the way down to 50 ohms depending on where
you look at it on the feed. Bird says the impedance is the same as the
load on either side of 1/2 wave lengths. It is not the same as the load
at other points other than 1/2 wave lengths. The other (not the same)
can be 50 ohms depending on where you look on the feed line.
This means you can show a pefect match to the rig with a 2:1 swr by
varying the feed length.
That is what an antenna tuner does. It electrically varies the feed
length as seen by the rig.
I not ready to give up yet and say you can not adjust the impedance
seen by a rig with a mis-matched antenna by varying the feed length.
your turn guys hi hi..

Correction. I said..

It is not the same as the load
at other points other than 1/2 wave lengths.

I should have said

It is not the same as the load
at other points other than either side 1/2 wave lengths.

I still think the impedance changes up and down
the line with a mis-matched load. From load impedance all the way down
to feed line impedance. Tell me where I am wrong in my thinking.
If the impedance does vary up and down the feed then the diff
impedance points can be picked by the feed length correct or not.

OK guys I think we have it under control now! Hi!

So Bob, am I right in understanding that it is a good idea to avoid line lengths of even half wavelengths if you can? That will actually mask the effects of a bad antenna.
And that the reflected power could actually be even greater than what you measure, unless the line is odd quarterwavelengths long?
Quite interesting indeed!

And Wes...your Smith chart talk is very interesting too, I just have to read up on my Smith charts before I can follow your discussion. But I will!

Thanks also to John for sending me a copy of a page in the Bird manual where there is a diagram for the required length of RG-8/U cable to equal 1/2 wavelength when added to the Bird43. (For frequencies up to 500MHz).
That was actually the diagram I was missing in the first place!

Thanks all,
Ingvar SM7DUZ

Wes

One more thing I would like to add. I have an antenna here that has a
bad match.
It's swr is around 2.35 to 1. The ft-847 cuts back on power due to this.
If I change the feed
length I can fool the ft-847 and get it to put full power out. Same type
feed line just change the length. Looks to me like the ft-847 thinks it
is seeing 50 ohms load when I vary the length.
Power out meter on ft-847 sure does change.

Yes Correct Ingvar. Actually I am glad you brought this all up. It makes
us all think
and learn. I am enjoying this discussion very much. Hope to learn more
myself.
I think if you only operate HF or only have matched antenna's in the
first place you would
not notice these things. Of course so far I seem to be the only one that
thinks this way hi hi.
I did see a presentation by ARRL at the S.E. Vhf Conference in Atlanta
that said the same thing I am
saying 2 years ago.

That is exactly the example I proposed previously and it works just as I said. If the load is 100+j0 and the line Zo is 50, then the SWR is 2:1 everywhere on the line (assuming no loss).

On the Smith chart, one complete revolution is 1/2 wavelength so if you make the complete circle, you obviously wind up back at the same place. That is the basis of the 'magic' 1/2 wavelength "impedance repeater" and Bird's statement that you quote below.

If you do not make a complete revolution you wind up with different impedance and it sure isn't 50 ohm because that is the center of the circle about which you are rotating. So you *never* see 50+j0 on a 50 ohm lossless line if the load is other than 50+j0. To be sure there are two points on the chart where the Z is 50 +/-j X and two others where the |Z| = 50, but the SWR is still 2:1.

If you should rotate only halfway around the chart (1/4 wavelength) then the impedance is 25+j0; still 2:1 in a 50-ohm system.

So yes, you can adjust the impedance seen by the transmitter by varying the line length but only to the extent that the new impedance falls on the 2:1 circle. You *never* see a "perfect match" in this situation.

Antenna tuners are another subject, but I will say that they do more than electrically varying the electrical length. The above example proves this. No matter what electrical length the cable is, the SWR never changes from 2:1.

Wes

That doesn't look like a synchronous detector to me. It's not a bad
circuit, but it has no synchronous oscillator to replace a selectively
faded carrier.

Instead it limits the carrier to recover it cleanly. This will work
only as long as the sidebands never approach the magnitude of the full
carrier. If they do (as they would in a deep fade) you'll get total
garbage coming out of the detector.

368. Helix antennas for hydrogen line (1420MHz) work

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-18 18:17:30 UTC
From: Ash <abuse@gravitywell.org>
Message-ID: <3A673336.267994D7@gravitywell.org>
Source record: 55365

Hi
I've been considering using 4 phased Helix antennas instead of a parabolic dish
since they are quite hard to get here in sweden , a 3-5meter dish that is...
I've only used my radioscanner for a couple of years but have been into amateur radio
and satellite work alot during this time and radio communication is my largest interest
since a few years back.
Now I'm tired of playing with weather satellites and such, and is looking to explore what
I'm
really interested in - space. And the waterhole looks like a nice spot to start, I'll be
doing both
hydrogen line work and seti search.
Although I'm an electronics engineer I'm planning on buying most of the stuff ,
from DownEastMicrowave I'm going to buy 1420-144RX downconverter (my scanner only
goes from 10kHz to 1300MHz) and the 1420ULNA <0.4dB NF pre-amp.
Some questions I have about helix's is how directional are they?
Phasing 4 would improve that alot (compared to just one) I guess?
I've seen on some helix designs some use a piece of metal from the last winding and
adjusting it
closer or further from the groundplane, is this necessary for a rx only antenna too?
Is it really possible to replace the dish with helix's? Otherwise I can wait on buying the
downconverter etc.
One other thing, for rx purposes I've been using standard home satellite - low loss 75ohm
cable
(14.5dB loss @ 500MHz compared to RG-214's 18dB loss @ 500MHz (per 100meter) with great
results
for years, and would very much prefer to continue so, will there be much loss jumping from
50 to 75ohm for
downlead only! the 75ohm will still have LNA / downconverter / mmic line amplifier in front
of it,
and on 144mhz the losses are minimal are they not?
I'd really much appreciate valuable thoughts and replies

Regards
Anders Gimseus

>And that the reflected power could actually be even greater than what you
>measure, unless the line is odd quarterwavelengths long?
>Quite interesting indeed!

Let me point out a difficulty with trying to realize a particular electrical line length over some distance.

For example let's assume that we are operating at 300 MHz (just to make the math a little easier) and we have a lossless transmission line with unity velocity factor.

The wavelength (L) is 1 meter, so a line one meter long will have 360 degrees of phase delay (when matched). Now an antenna probably will be further away than 1 meter so let's say (again to simplify the numbers) that the line is 50 meters long. The phase shift in this line is 18,000 degrees or 50 wavelengths so the line "repeats" the load Z at the input.

With the hypothetical 100+j0 ohm load from the previous examples, we see 100 +j0 at the input. So far, so good.

Now let's QSY up to 301.5 MHz: L is now 0.995 meters so our 50-meter line is 50.25 wavelengths long. That's 100 and a half trips around the Smith chart. Our 100 +j0 load looks like 25+j0 at the line input. We picked up a quarter wavelength of cable just by moving frequency by 1.5 MHz (0.5%).

This is what is called the "long lines effect" and points out the difficulty of trying to use a "magic" length of cable as is so often recommend in amateur discussions. This can be even more complicated it thermal effects and measurement tolerances are thrown in.

If bandwidth of any significance is desired, then the matching should be done as close to the load as possible and the balance of the transmission line operated in a matched condition.

Probably will be fine. I assume this amp is for relatively low frequencies; the only problems I'd expect have to do with changes in capacitance seen at the transistor's collector (drain?), and that depends on the heat sink, the board, etc. -- in short, the whole environment around the transistor. At 4MHz - 7MHz, I wouldn't expect a problem, but at 440MHz, positions and lead lengths are critical. As with most things, there's a lot of gray area and YMMV.

Cheers,
Tom

Strong agreement from here about what Wes wrote. Some more food for thought: that 100+j0 ohm antenna, fed instead with 75 ohm line, results in a constant 1.33:1 SWR on the line, just as it results in a constant 2:1 SWR on a 50 ohm line. However, if you plot the effect on a Smith chart normalized to 50 ohms, THEN you'll see a circle centered on 75 ohms, passing through 100+j0 ohms, and also passing through 56.25+j0 ohms. THAT point is rather a low "SWR" to a transmitter that likes to see 50 ohms, or for that matter a pretty well matched load to a length of 50 ohm line, and would result in a low SWR on the 50 ohm line.

So...by changing the length of a uniform impedance, lossless line, you won't change the SWR on that line, but by changing the length of a section of line of one impedance, you may change the SWR in another line of a different impedance that it's connected in series with. (There won't be an effect only if the SWR on the line whose length you change is 1:1.)

Cheers,
Tom

http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=1208881823

Sorry for the cryptic subject. It just seems this would be the basis for a really neat
homebrew transmitter or receiver for portable use. This item is in reality an
International Crystal model 2400-0-2148 deviation meter. At least that's what I
think it is! It's in a nice metal cubic case 8x8x8 with latch. There is a deviation meter,
a channel selector, and a fairly decent vernier dial. The Channel selector has a
Weston thermometer built into it! Inside are 24 ceramic crystal sockets that have
(alas!) been relieved of their crystals. There is a very high quality 24-position
rotary switch and 3 very high quality ceramic variable capacitors, and a really
solid coil form. I would consider this a parts set, given the cost of recrystalling
it. But still a nice little unit to build into something. Could be a really nifty retro
portable tube ham receiver, or a transmitter-receiver. That's why I stuck it in the
'Transmitters' section - I think it would make a really cool little portable rig. The
vernier is smooth and more than adequate to track 40m CW around a fixed
rock transmitter. Also has a heavy carry handle on the case, and S0-239 antenna
connectors on the top - really perfect for a little rig.
Lotsa neat parts! Even has a robust battery holder inside.

Sorry for such a long post.

Take care

Richard,

Yes, I got it working, with Bob Camp's help. It certainly didn't work
the way I thought it did, according to my reading of the product spec.
I particular, the iOUD

The trick was initializing it TWICE. The first time just to get it changed
to INTERNAL update, and the second time with all the right bits and
an IOUD to make it take. I couldn't get it to work at all in internal
update mode (the default!).

I also have PIC code. Mine is 16F877 code. Let me know what
would be helpful.

Richard,

I have not found the part to be very easy to damage. It seems to be about as rugged as the rest of the stuff on the board. What I do find as a problem is that the doc's are to long and to hard to read in one sitting ....

Bob

379. Re: Bird Thruline wattmeters

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-19 01:05:16 UTC
From: Bob Dodson <wb5apd@alltel.net>
Message-ID: <3A6792CC.C27095F6@alltel.net>
Source record: 55376

Well folks I never said you could actually change a swr by the feed
line length, only the perceived swr by a rig or a swr meter. No, in my
stated instance you will never see a perfect match at the transmitter
BUT you can see a vastly lower swr. That is all I have been saying. I am
not suggesting you can tune an antenna or change a swr by line length,
just that the impedance will change down the line therefore it matters
where you look on the line to see the true FULL reflected power.
If you read Wes/Toms statement below carefully I think they agree with
this ?? Like I said if you have no reflected power then there is no need
to worry about line length. Since conditions can change
and you might develop a swr, then the feed length needs to be taken into
consideration to see how much reflected power there really is, and
where to look on the line to see the FULL reflected power for a given
freq.

I will let Tom answer for himself, but I disagree.

One last time.

If the SWR on a lossless line is 2:1 (or any other value) at one point along the line, then without introducing some other matching element, it is 2:1 (or the same value) at every other point on the line. Period.

If the measuring equipment (either the Bird or the built-in SWR measuring system) says or perceives anything differently, then that equipment is providing inaccurate results. Period.

It is entirely possible, even likely, that the transmitter will prefer some value of impedance over another, even though they have the same SWR. Therefore, pruning the line length may (probably will) change the output power. If the output power changes, then the forward power and the reflected power change proportionately but their ratio does not. If the instrumentation says something differently, then it is wrong.

Well why Australia? Radars used for what?

We live near a harbour and, judging by the different sizes of the various antennae, there appear to be many types of radar used on ships. On one occasion I detected radar pulses from a naval ship on a regular car radio, while it was tuned to a local AM broadcast station!

Also the airport has several radars. There have been some comments that some can be picked up i.e. they interfere with, some of the cheap CB (27 Mhz.) handheld units. Probably just 'blocking' the front end of the CB receiver?

And a local broadcasting station has a weather radar system. I suppose you could detect that if you wished?

Question is too vague. And would appear to be not 'normally' the kind of thing 'Amateur Radio Homebrewers' are constructing?

384. can you help with a question

Hi gang,
I'm looking for a few (3 or 4) old Motorola HEP 590 ICs. They were a metal can diff amp type IC available around the mid 70's. I can come up with an ECG/NTE sub that is similar, but I would really like to get my hands on some of the original article. Anyone got some gathering dust?

tnx es 72

Source record: 55383

A point that might have been missed is that "50 ohm" lines often aren't really 50 ohms. Manufacturers can be pretty sloppy, and 10 ohms one way or the other isn't unusual. As Tom pointed out, you CAN change the SWR on the internal Bird line (which is what it measures) by changing the length of a non-50 ohm line between it and the load. If you see the SWR (or the ratio of forward to reverse power) change when you change the line length, you've either got current on the outside of the line causing it to be part of the load, or your transmission line isn't really 50 ohms. (I'm assuming here that the loss in the added or removed sections of line is negligible. Otherwise, increasing the length of the line to the load will decrease the SWR.) Just because the line says 50 ohms doesn't mean it is.

Roy Lewallen, W7EL

Sorry, this may work with exalted carrier detection (BFO set
to zero beat the carrier using a product detector), but not
with an envelope detector. W3JDR is correct.

The amplitudes of both sidebands must be equal and the
carrier voltage must be at least twice the amplitude of
either sideband for distortionless detection with an
envelope detector. [The phases of the carrier and both
sidebands must also be in the proper relationship.] Tuning
off to one side with an envelope detector produces the same
type of distortion as selective fading. You need to look at
the envelope detector not as a rectifier, but as a mixer,
where the sidebands and carrier mix to produce a mix of
audio and RF signals. Viewing the diode as a square-law
device is the easiest wayu to demonstrate this
mathematically.

>Some questions I have about helix's is how directional are they?

For any antenna with a distinct main lobe in the radiation pattern, you can get an estimation of the solid angle of the main lobe by dividing the solid angle for a sphere by the absolute gain (_not_ dB) over isotropic radiator.

>Phasing 4 would improve that alot (compared to just one) I guess?

If you maintain "optimum" spacing (i.e. maintain a clean pattern), the gain would increase by nearly 6 dB and the radiation angle in both horizontal and vertical pattern width would be halved compared to a single antenna.

For radio astronomy, it can be advantageous to use larger spacing, thus the radiation pattern will contain a lot of "fingers", with nulls between peaks. If there are only two point sources with some angular distance between them, then a narrow finger can be pointed towards the wanted signal and the null towards the unwanted source. However, with more than two point sources, these fingers cause a lot of aliases.

I think you have something wrong with your math. Otherwise, how on
earth could you possibly receive CHU with an envelope detector on
7.335? It has only one sideband.

Have you never tuned an AM signal with the carrier near the edge of a
narrow filter?

And what did it sound like?

You only need one sideband with the carrier. You can tune to one side. Yes, sometimes you do get distortion due to the carrier phase change at the filter edge, but it's not always severe enough to cause bad distortion. That's a filter issue, not a detector issue.

It's nigh-unto impossible to work on fine-pitch SMT with conventional soldering tools. Heated air (using a proper size shaped nozzle) works far better. Try to find a local electronics shop (TV repair place?) which has the right tools.

I broke down and bought a used MTR5000 rework station ($3K used) for my ham shack. Now I can build/rebuild anything!

Hi

trying to repair my HP 8640A signal generator (with option 002 installed) I have ripped off some of the wires soldered to the connector board (part number: 08640-60302 A1544-4) which is attached to the AM /AGC/RF AMP Assembly. Can someone send me a copy of the part of the schematic which shows the assignment of the wires? If the color code of the wires is the same with all 8640s the color to pad assignment would also do.

Peter

Hi,

A few days ago I posted a request for information on the above subject and have since received a reply from Peter Chadwick. As he is unable to post to this group, I have his permission to repeat it here.

++++++++++++++++
Start of repeat.
++++++++++++++++

Hi Joe,

Well, the Plessey 'Groundsat' on frequency repeater used a direct conversion receiver with I and Q channels. As a result, the local oscillator was on the receive frequency, and was remodulated by the received signal. By amplifying the LO and putting it back to the antenna, you got an on-frequency repeater. The problems are that the transmit power is limited by the dynamic range of the mixers in the receiver, and you have to get the phase shift of the modulation through the system correct so that it doesn't cancel the modulation at one extreme, or oscillate at the other. In order to do FM with analogue direct conversion, you need to do something clever in the demod: as I remember, Groundsat used AGC on each IF strip, and then differentiated the IF and mixed it with the other channel - basically getting I squared plus Q squared. This needs very accurate matched gain control in the two channels.

Strangely enough, it was never a commercial success, and I've never really understood why that was. There was a lot of work done at Roke Manor in those days on direct conversion: as Plessey Semiconductors, we were involved a bit. I guess the patents must have expired by now.

Hope this is of interest.

73

Peter G3RZP

++++++++++++++
End of repeat.
++++++++++++++

All of which raises some interesting points about FM direct-conversion receivers and front-end design.

Cheers - Joe, G3LLV

For resistors, it's generally not too hard to just heat both ends with an iron and remove it with tweezers (or very fine needlenose, perhaps). I generally just heat one end then the other, back and forth, till I can push the R off its pads with the iron. Clean the pads on the board w/ solder wick before re-installing the resistor .. or better, use a new resistor. ICs are more problematic, but not impossible with a good iron and solder wick and patience.

Cheers,

Jake,
I'm not sure which math you're referring to...please clarify.

In any case, a carrier with one sideband is not AM. I would happily agree to call it a special case of AM., but it is not AM. It does not produce an envelope that is a faithful reproduction of the original modulation. It 'works' sufficiently well to produce communications qualty audio at moderate modulation percentages, but it distorts in the troughs as modulation approaches 100%. Tuning the receiver off-center in order to pass more of the modulation bandwidth of one set of sidebands will produce better frequency fidelity, but the distortion will hardly qualify as 'hi-fi'.

Yep, that's the way I often do it too. Great minds and all. If I only have one or two to take off, I just use a single iron (sometimes adding a bit of solder, bridging the R end to end to heat both ends at once). Seems like the only problem components are the ones that are glued down (typically on the "bottom" of boards that are wave soldered).

Cheers,
Tom

Peter,

I hope your question has been answered. The answer is NO. Transmission distance is a function of propagation, not antenna length. Propagation at 2 meters is most very short range. Yes, there are some long distance QSOs on record but they are not because of long antennas. Rather the antennas used have gain, brought about by reshaping the transmitted wave.

Connecting a long wire antenna has some negative benefits as well. If your long wire isn't carefully cut to be a multiple of a quarter wavelength it may have a very high impedance at its end and cause very high SWR.

Many construction projects will list a parts source. If you are going to do a lot of homebrewing, become a parts-catalog collector, and become familiar with what each distributor carries.

A great resource to look up nearly any company selling part of interest to hams is found on the ARRL web site at:

http://www.arrl.org/tis/tisfind.html

This database can be searched by either any word in the database or by category. If you want a list of companies selling solar panels, type in solar panel in the search box that is down the screen a bit. One of the more popular parts suppliers is Digikey. To get a rather large list of other suppliers, type in COMPONENT>COMPONENT SUPPLIER in the search box.

The categories list is shown at:

http://www.arrl.org/tis/tisfind.html#cats

Have fun with the searchable, categorized database.

Bruce and the assembled multitude,

I agree with the idea of simply putting in some fairly modern mixer diodes. That's what I finally did and it worked out well, mainly thanks to all who pitched in with helpful tidbits of information. In all of the stuff I came across I never did find a spec on the old mixer diodes.....

Thanks!

Bob

Hi Mat,
if u are referring to police radar, heres a circuit diagram ive had floating around for a while now. Its designed to pick up X-band radar (10.525 GHz) which is now obsolete, however if you use the included formula to change the capacitor lead length, you might be able to get it to work for K or Ka band (K band is handheld radar 24.150GHz, and Ka band is photoradar 33.4->36 GHz). The formula is log10, and in inches.

Ive never got around to making it myself, as im not sure what units the capaciors values are in. The detecting capacitor is listed as "0.22" which i assume is microFarad, as the one capacitor that does have a unit listed is in uF. Anyone have any ideas on this given that it is to detect ~10GHz? It also doesnt say what type of capacitor to use for the detector (i assume a greencap?)

It would be great to get working, it would be immune to radar detectors, as it lacks the leaky oscillator they rely on.. plus its so small! :) The downside is it might not work too well, let me know how u go if it works!

cheers,
Whiskey.

> with an envelope detector on 7.335? It has only one
> sideband.

Because it only _has_ just ONE sideband. If the other were present, but at a very small amplitude, you would get what is known as quadrature distortion. CHU is not modulated deeply either.

> Have you never tuned an AM signal with the carrier near
> the edge of a narrow filter?
> And what did it sound like?

Distorted!

> You only need one sideband with the carrier. You can tune
> to one side. Yes, sometimes you do get distortion due to
> the carrier phase change at the filter edge, but it's not
> always severe enough to cause bad distortion. That's a
> filter issue, not a detector issue.

Forget the phase change for the moment. Just assume the filter amplitude response is not symmetric with respect to the carrier. You now produce an in-phase component that is reduced in amplitude. But you generate a quadrature component too. If the quadrature component is excessive, it can produce considerable distortion. You can demonstate this mathematically with nothing more than trigonometric identities. [And while it took only a half sheet of paper to show this with my scribbling, I am certainly not going to take lots of time to type this in with proper subscripts, superscipts, anmd greek letters. It does make a good learning exercise however.]

If you wish to read more about this, I suggest:

Rohde, Ulrich L. and T. T. N. Bucher: "Communication Receivers: Principles and Design," McGraw-Hill, NY, 1988, pp.362-376.

I am sure the later edition of this book covers this issue too. To quote one pertinent section:

"To avoid quadrature distortion, we try to tune the carrier to the center frequency of the filter, and design our band-pass filters with complex zeroes and poles distributed symmetrically about the filter center frequency. Then the demodulated signal is distorted linearly in amplitude and phase by the characteristics at the USB frequency offset from the carrier, and no quadrature component is introduced. Standard filter designs discussed earlier are based on seeking such characteristics."

The reason I earlier mentioned exalted carrier reception (not an envelope detector) is that the supplied carrier (BFO) when applied at a much greater amplitude than the received carrier tends to reduce the effective modulation index of the signal. Without this, problems occur when the negative modulation index approaches 100 percent. You might note that W3JDR in his reply stated that when using a carrier and one sideband with an envelope detector, the problems occur on the modulation troughs.

If you include the effects of different phase shifts when the carrier is offset from the center of the filter response, you can get far more distortion. This is the distortion found in selective fading oh HF radio paths.

The original poster was looking for high-fidelity detection of AM. An offset filter response is not the way to achieve this.

Henry,

I used the Agilent HSMS 2812. They seem to be the middle of the road part. The 280x and 282x parts are a bit to either side of them in terms of forward voltage. The 282x's might do a better job, but who knows ....

The other major item in the decision making process was that they came in as samples at work .... hate to spend a dollar or two to fix up a 8590 :)

One thing I figured out a bit late - the right way to do it is to cut the old diodes out rather than unsolder them. If you chop the old ones you have a better chance of keeping everything on the duroid from moving around. Also since the old diodes seem to be welled (rather than soldered) into the end blocks you have to do some chopping either way.

Thanks to All!

Bob

Ive had some sucess with switching inductance taps with pin diodes also
look out for self biasing the varicaps operate back to back.
Varicaps in parallel reduces equivilent series resistance and increases
Q.
For super octave operation try an L varicap t or pi network with more
than one stage series loss goes up but tuning range increases.

You don't make it easy.

I use an inverted "L" for 160, 80 and 40 meters. It's a half wave on 160 and voltage fed on all three bands using an "L" network that is remotely tuned with a motor driven vacuum variable and a Ledex driven switch for the inductor taps. My antenna presents about 2600 ohms on 160, 1800 ohms on 80 and about 700 ohms on 40 meters, making it possible to always keep the capacitor on the antenna end of the inductor so that it doesn't have to be switched. The "L" network was calculated from the measured values of impedance and worked right the first time. It will present a match on any frequency on any of the three bands with just varying the capacity with a single tap on the inductor for each band. Settings vary a bit depending on ground water despite a counterpoise and a 60 foot well casing beneath the tuner. Still have no difficulty and the antenna is quite competitive on all three bands.

You don't NEED an antenna tuner that will match anything to anything, (Although an "L" network can do that,) you just need one that will match your antenna to the rig.

Hi

I have an application where there are already voice radio's in place (CB like) radios.

I have to transmit an alarm tone via the radio link to a distant station. The radio network,
i.e. relay towers etc. are already in place for the exisint voice communications. My question
is this, to send an alarm signal across the voice channel, is this as simple as making an FM transmitter
on the same frequency as the existing voice comms and feeding the alarm signal into the FM transmitter?

It seems that this is all that is required.

Any comments are welcome.

Thank you
Pieter.

I haven't seen it myself but I believe the G3XJP auto-atu was
published in a recent issue (or issues?) of RadCom.

depends whether you want automatic tuning or not
please check the last few issues of Radcom 2000, if it should cover
only one band and this band is not 80 or 160m it seems no reason why
it cannot be adjusted once and for all, to cover more bands you can
use pre-set tuning conditions

Thank you for your comment Harold.

When I think about it, I'm really after building myself 2 remote ATU's for an inverted "L" antenna. One for general coverage receiving, the other for transmitting/receiving on the ham bands.

Now that I've directed myself properly on that issue, I can appreciate that's it's quite likely that the only thing needed to make an ATU for the ham bands, is a tapped fixed inductor and fixed capacitors and a set of relays (manually pre-set as G3SEK mentions). Yes, that could be the answer. I wonder though if I would have a problem if I chose not to have a variable capacitor in the "L" network. Perhaps on the LF bands there would be a problem with narrow bandwith, especially since the maximum length of wire I could get out is about 78 feet. (But given a mediocre earth connection maybe not). If narrow bandwith was a problem maybe I could arrange to toggle between 2 capacitors.

I'd like to operate with an invered "L", but I wonder about the earthing losses. I've got Reg Edward's "endfeed.exe" program (which I think is what

I need to compute the L & C for the "L" network") but I'm unsure as to what earthing requirements in practice I'd need to get acceptable efficiency. (And I muse, what is an acceptable radiating efficiency, 75%?)

Perhaps I should try to get a copy of Ian Whites article. I take it that it does cover inverted "L" antenna's and answers some of my concerns.

(Anyone in UK willing to photocopy and post me December 2000' 'In Practice' column in RadCom that covered the "manually pre-set, but remotely operated" option?)

For the "endfeed.exe" program:

Yes it does. It recommends the use of ENDFEED as a design tool, and
makes some suggestions about earthing.

http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=1209301289

The above link is for a beautiful homebrew 8-tube ham receiver. I bought it back in 1975 as a teenager and had it ever since. It's never been turned on because the power cord is frayed, but judging by the construction I'm sure it's well built and will run again. I set a reserve on this because of my personal attachment to it. But I will NEVER get around to restoring it, so it's time to pass it on to someone who will.

Take a look at it - this is a NEAT old 8 tube radio.

I have to "toggle" my motor driven vacuum variable a couple of times going from one end of 160 meters to the other to flatten the line, It's fairly sharp even with 250 feet of wire out there. (Conversely, 40 meters is way below 2:1 all across the band with a single setting) and interestingly, for my particular setup, the capacitor values for the top end of 160 and 40 meters are nearly identical. 80 is off quite a bit. At any rate, realizing that not everyone has motor driven caps, you could probably do a suitable job of it with switched caps, particularly if you can switch them 1-2-4-8 style to get incremental values.

If you're loaded with relays and room is not a problem, simply put in the capacity you need for each band made up of fixed and variables and switch the whole thing with a rotary wafer, you only need to tune it up once unless you decide (or mother nature decides for you) to change antennas.

I read Peter Rhodes articles on the homebrew tuner in RadCom. I marvel at his stamina and ingenuity, I actually thought about his technique for some high power solid state low pass filter caps that I thought I needed but I probably don't have the patience for something like that. I do think his major contribution there was the statement about not NEEDING a tuner that will match anything to anything, just a tuner to match your particular conditions.

Depends on what you can accomplish. 120 radials are great. I settle for an elevated counterpoise that extends the full length of the horizontal section of my "L". I know it would reduce my ground losses to have more, but there's a wife and neighbors to live with. Besides, I disconnect my counterpoise

when I want it to use as a 60 KHz antenna for calibrating my standard. (Once a year?) Fed against the well casing, it gives me all kinds of signal from WWVB. Get something up, even 25 percent effeciency is heads and shoulders better than no antenna at all. Good Luck.

I have generally heard that crystal filters shouldn't have more than +10dBm
or signal applied to them; if I am wrong, anybody can feel free to correct
me. About mechanical filters, I am not sure. In reference to the input
intercept, I believe that you are talking about the 3rd order intercept. I
think that you would be ok, working with a high level mixer, in the IP3
range that you described, because the IP3 is a figure of merit, at an
extrapolated point where the distortion products "catch up" with the desired
signal at the I.F. output of the mixer. Again, if I have missed the point
here, feel free to correct me.
Anyway, since the IP3 is a figure of merit, and you hopefully wouldn't
see a 40 to 50 dBm signal at your mixer input (this corresponds to 10 Watts
and 100 Watts of RF!), you should be ok.

I had an application once where we had 18 un-attended locations
that needed to be remote-switched simultaneously, and rapidly (ie,
to the second). We installed scanners at the various locations
fix-tuned to the local paging system (analog) with the audio
feeding into a touch-tone decoder. (This was in the early 80s
before you could simply walk into RadioShack and buy all the
pagers you want) Any person, throughout the organization could
simply dial in via telephone and key in the appropriate codes to
make the switches function. The tone decoders were the little $10
kit circuits you see advertised.
It worked quite well. Single tone switching, especially in
crowded bands or on the same channel with audio, isn't very
reliable and is prone to alot of glitching. Standard touchtones
are reliable and the equipment is cheap.

==========
With defunct floppy drives available all over the place ,there are may
opportunities to get a functional stepper motor . These usually make 1.8
degrees per step or 200 steps per revolution. Or covering the range of a
variable (plate) capacitor in 100 steps. If this resolution is insufficient
,a coaxial reduction gear 3:1 or 6:1 can be placed between the stepper motor
and variable capacitor.
These reduction gears can be found on old valve equipment (Heathkit etc)
,but are also still available as new.

Note: Some stepper motors have 3.6 degrees per step, resulting in only 100
steps per revolution.

Stepper motors can be triggered by a 555 timer type of pulse generator (with
transistor power output stage)
Pulse rate can be made variable and motor rotation can be reversed by a
simple switch.

Remote feedback of the capacitor's position is simple by means of a good
quality wirewound potmeter (ten turn if available) mechanically linked to
the capacitor ; the potmeter forming 2 resistor legs of a remote bridge
circuit with moving coil meter or digital voltmeter.

For rotating vacuum caps you might need a stronger stepper motor from those
good old 1970-80s 8inch dics drives . Remember the CDC and the like
computers ?

From: "W3JDR" <j.r@usa.com>
Subject: Re: AM Detector Info
Date: 20 January 2001 01:48

Jake,
I'm not sure which math you're referring to...please clarify.

In any case, a carrier with one sideband is not AM. I would happily agree to call it a special case of AM., but it is not AM. It does not produce an envelope that is a faithful reproduction of the original modulation. It 'works' sufficiently well to produce communications qualty audio at moderate modulation percentages, but it distorts in the troughs as modulation approaches 100%. Tuning the receiver off-center in order to pass more of the modulation bandwidth of one set of sidebands will produce better frequency fidelity, but the distortion will hardly qualify as 'hi-fi'.

==========
Don't want to be pedantic but the above sounds like the usual confusion of terminology.
AM means Amplitude Modulation

It is applied in various ways.

1) To a carrier with both sidebands generated : DSB most broadcast stations outside the FM bands
This mode is by amateurs usually referred to as AM

2) Single Side Band with suppressed or reduced carrier

3) Independent sidebands with suppressed or reduced carrier
Here each sideband transmits different information

All of the above modes involve amplitude modulation.

Pete,

The +10 dbm limit is a reasonable one for normal monolithic filters. I have seen discrete crystal filters that seem to be quite happy with +25 to +30 dbm on their input. Of course your government and mine paid some cash to make them that way....

A crystal is generally damaged by power dissipated in the resonator. In the case of a filter the power applied may or may not wind up in a resonator. When the signal is far enough off channel it's just reflected back out of the filter. With a signal directly on channel at least part of it is passed through to the load.

I suspect that as time has gone by the monolythics have gotten better as far as power handling. I see an awful lot of parts that started out as discrete designs and now are being produced as monolythics.

I have not seen to many IF amplifiers or mixers that will put out > +20 dbm though so I'm not sure how important the issue really is.

Henry,

No need to panic. Sounds like everything is working fine.

4,999,999.8 / 5 = 9,999,999.96

The location of the decimal is the problem. The error is past the
resolution limit of the counter at 1 MHz.

I find it easier to do the math this way:

-0.2 hz error at 5 MHz / 5 = -0.04 Hz error at 1 MHz

Also since everything that a counter does is +/- 1 count on the least
significant digit you may or may not have an error of 0.2 hz at 5 MHz.
The error could be anything from -0.1 to -0.3 Hz.

Test equipment is so much fun :)

Now for the real question .... how do you set the HP 105 on frequency
to better than 0.1 Hz ? These days GPS seems to be the favored
approach.

Hope this helps.

> Any thoughts about this?
>
> Ralph

==========

I recall reading some articles that show different crystal filter designs
show different overload limits depending on how the input section inside the
filer is configured.

There are other mechanisms of distortion in the crystals themselves so
even the best topology has an overload limit.

Most common crystal filters have an intercept point around +15 to +18 dBm
according to an article I have here in front of me.

This is from Communications Quarterly, Fall 1994. Page 89.

The complete article, by the way is a discussion of ultra high dynamic
range front end design, and how to improve the performance.

One scheme I remember was to use a hybrid splitter after the first mixer
and then feed TWO identical filters. Use another hybrid to combine their
outputs and you wind up with a higher dynamic range filtering system.

Using the hybrid splitter terminates the mixer into 50 ohms while
allowing the filters to be connected DIRECTLY after the mixer. So, by
placing the filter as close to the mixer as possible, AND splitting the
signal so that a lower level hits each crystal filter, one can obtain the
maximum possible dynamic range for the complete system.

==========

Expensive, and probably in most system designs the limiting factor for
performance will be the mixer and phase noise floor on the synthesizer.
Those limits are usually reached 'way before most crystal filters are
overloaded.

Still, for a homebrew design, a VERY interesting concept.

If the counter really displays frequency to 0.1Hz resolution, then the
gate time must be (at least) 10 s. Unless the gate time is
synchronised with the waveform, the last digit is always suspect (+/-
1), thus, if you perform the measurement multiple times, you might
also see 4999999.7 or 4999999.9 and 999999.9 or 1000000.1.

>i'm baffled: 4,999,999.8/5 = 999,999.6, and wonder why i don't get that on
>the 1 mhz output..

I know that you are using strange units such as feet and ponds on your
side of the Pond, but I did not know you are using different
arithmetic too :-). Using a non-American calculator, I get 4999999.8/5
= 999999.96. Using a sufficiently large number of repeated
measurements, a frequency counter with 0.1 Hz resolution would display
6 out of 10 cases 1000000.0 and 4 out of 10 cases 999999.9 (unless the
start of the gate time has been synchronised to the waveform).

I don't have specs for the "a" model, but the specs for the "b" model show that if you have the standard timebase, you may have around 0.1 ppm tolerance, or +/- 0.5 Hz at 5MHz (0.1 Hz at 1 MHz). Add to that the +/- 1 LSB standard for counters gives a possible error of +/- 0.6 Hz at 5MHz (or 0.2 Hz at 1 MHz). Off hand I'd say the counter was working well and the readings are reasonable.
(BTW, if you haven't caught it already, 4,999,999.8/5=999,999.96)

A diode ring-mixer (DBM) should be suitable for the job. It is
difficult to recommend a specific device without knowing what
you intend to do with it. The Mini Circuits SBL1 and the
M/A-COM MD108 are popular mixers for HF/VHF.

The original poster asked how he could build a hi-fi AM detector for his communications radio. It is a fair assumption that he wants to listen to "AM" in the classical use of the term. I don't think he was talking about SSB, ISB, DSB, or some other form. A subsequent poster explained how better frequency response can be gotten from a simple envelope detector by tuning the receiver off-carrier. Later posts explained that an AM signal that is thus mistuned has a distorted envelope because the signal is no longer 'AM' once it hits the envelope detector. Only AM has a linear envelope.
SSB, DSB, ISB, and other modulation forms may 'involve AM' as you say, but they are not 'AM'. QPSK, QAM, and many other complex modulation forms also 'involve' AM, but they are not AM. AM is concisely defined in most communications texts as a linear modulation of an RF carrier that results in a spectrum that has a carrier component and 2 sets of sidebands with well-defined and unique amplitude and phase relationships with respect to the carrier to and each other. By it's very nature, it produces an RF envelope that is a precise replica of the original modulation. None of the other forms you mentioned deliver a linearly modulated envelope that can be demodulated with a simple envelope detector.

Hi

I'm (very possibly) going to try to build something (small remote-control ATU for receiving purposes.) employing a stepper motor. Stepper motors are easily obtainable and cheap (from old floppies). However, obtainability is one thing, matching a salvaged stepper motor up with a suitable controller is another.

I've got stepper motor in front of me now, is there any way I could fathom out a circuit to run it?

It is made in Japan, but also identified as Applied Motor Products Inc, Scotts valley CA, DC12v 1.0A/ï¿½ 1.32 Ohms 400S/R. Out are 4 wires, red, blue, white and yellow. P/N 63-004280-00(5016-907)REV. Also has on B46-90.

Are there any general rules (or indeed databases) which one can use to aid in getting a motor, one happens to have at hand, up and running?

Thanks if you can help.

Rich.

Please note: This post has been crossposted, you may wish to respond only in your regular forum. I crossposted thinking I'd widen the net of available help.

I'm so pleased you added that last line - (with a simple envelope
detector) Otherwise I would have trouble reconciling this thread with
Short Wave SSB broadcasts; which do a great job, including music.
My Kenwood Ham gear has trouble with music on SSB, but using a Short
Wave receiver (HF-150) in synchronous AM handles SSB broadcasts just
fine.

The Mini-Circuits SRA-3, SBL-3, TUF-3, TFM-3, GRA-3 are all good mixers.
The SRA-3 would be my choice, since it is specified to operate down to
25KHz. I have used the TUF-3 with equally good results. The midband
conversion loss of these mixers is in the 4.7 to 5.0dB range. Since these
mixers are passive types, the noise figure is approximately the same as the
conversion loss, just slightly higher.
I have been using these mixers in my own designs for a few years
now, and with no RF amplification ahead of them, you are looking at a
Minimum Discernable Siglan of .02 to .04uV.

Source record: 55249

There were two articles that came to mind when I saw this post; one of the articles used a 4066 analog switch at a detector, using a comparator to gate the switch on and off. Supposedly, this detector had wide bandwidth and low distortion.
The other detector was pretty interesting; a fellow in Canada came up with a design that used a Phillips FM I.F. strip, and took the RSSI signal and ran it in to an antilog amp. The result was that this strip could demodulate AM and FM. The FM signal would be taken of the demodulated output of the chip, while the AM signal would be taken at the output of the antilog amplifier. I have been meaning to build this circuit for the last 5 years or so. Maybe someday.....
Now, if you really want to keep it simple, you could use an absolute value detector, which uses an op amp, with diodes in the feedback loop. This type of detector has a threshold of around 2 or three millivolts, and it sounds great! The key is to use an op amp that has a large enough bandwidth to operate properly at the final intermediate frequency. I DID use a TLO72 and an LF353, both Radio Shack stock items, and they were fine as a detector for the MW band, so a 455KHz I.F. signal would present no problems. I had actually intended to use this circuit in a radio design, but when I discovered the Phillips TDA-1572, I abandoned this approach. The receivers that I have designed with the 1572 have a distortion of .5% at the audio output.
On a final note, the AOR-7030 receiver uses this device in the 2nd I.F. strip; this device is one of their claims to fame.

> > Anyone made, or know the wherabouts of any constructional details for a
> > remote-controlled ATU for an end-fed wire antenna?

I used to have a 130 foot wire at 55 feet. It was end fed on 80 using a series 120 pF fixed
vacuum capacitor and an adjustable shunt inductor from the wire to "ground" ("ground" was
the top of the tower). The adjustable inductor was a homebrew 6 inch diameter coil made
of 1/4 inch copper tubing with taps connects to a big rotary switch of the type used for
bandswitches in linears. The switch was driven by a rotary solenoid. Each pulse moves
to the next tap. I had taps every 100 kHz so I could have virtually 1:1 VSWR at all
frequencies.

Before building this, I measured the wire impedance with a noise bridge located at the top
of the tower. I had to build my own because it needed to be able to accurately measure
a 3000 ohm impedance and be remotely controllable from the ground).
This enabled the tuner to work the first time I put it up. (No climbing the tower and
tweaking it!).

I also fed it on 40, where it coincidentally also needed 120 pF, but of course, less inductance.
In general, the series cap would need to be bandswitched.

1. If this is a bipolar stepping motor then there will be 2 coils and the 4 wires will represent the ends of the coils. The first step is to find out which wires are 'paired.' Do this by testing the resistance between each wire and the remaining wires. When the wires are paired you will see 1.32ohms (approx) - or alternatively you should see infinite resistance.

2. If (by any chance) you find that a wire is connected to more than one other wire and one of the combinations has twice the resistance of the other combinations, then you are dealing with a unipolar stepping motor. These work on a different principle. [They are easier to understand and you might find it easier to learn how to use one of these first before moving on to the bipolar type.]

3. The basic action of the stepping motor is that current passing through the coil energizes the magnetic field which causes the permanent magnet at the core to take up a fixed position. All you have to do for your first experiment is choose ONE set of the paired leads - connect them to a 12Vdc source, and watch the motor move to a fixed position.

4. Disconnect this and do the same with the other pair. The stepping motor will move to a different position.

5. A stepping motor driver circuit basically does exactly what you are now doing manually. It just switches the current off on one coil and energizes the next, and so on.....

6. There are a couple of complications you should know about.

7. A unipolar stepping motor is simpler. It has 5 or 6 leads and the coils are center-tapped. The way to use this motor is to put the common [center-tap] line at 12Vdc, and then ground each of the other ends of the coils in turn. [There are various modes you can use - such as energizing 2 coils together - but this is the basic idea]

8. A bipolar stepping motor is more complicated, because there are only (in your case) 2 coils - so you have to REVERSE the direction of current across the coil to get the necessary 4 phases of stepping.

9. Armed with this knowledge, just repeat the experiment above but test for 'reverse' current across the coil too. If you stick a pointer (such as a chopstick or needle) on the spindle and record the position - you can easily work out from the above which order the coils need to be energized in to give the smooth motion you require.

10. When the coils de-energize, there is a considerable back EMF as the magnetic field disintegrates [you will probably see sparks as you take the lead off the terminal]. When you design the driver circuit you need to include snubbing diodes so the reverse current can fly back to source.... otherwise you will fry the transistors [which are usually darlington-pair transistors.... i.e., a darlington pair in the same package]

Have fund - and EMail me if you need any more hints.

Best regards, Roy G0WMF / 7J1AUA

Hi

Problem about crossposting initially, (as I did) is that if folks choose to reply only in their forum things said can get duplicated, it's better if everybody knows what in totality is being said. Way to do that is to crosspost replies to all the forums, but I wonder if that is bad netiquette. Perhaps when one initially crossposts one should direct folks to reply to a specified forum to keep all the messages together, without duplicating the messages all over the forums. But in that case some folks might not want to subscribe to a new forum. (Is it bad netiquette for continuing posts to be in more than one forum?)

Well, in this instance I think I'll suggest any future posts be posted to rec.amateur.homebrew, so I and others only have one forum to look at, and replies are seen in total, but it's just a suggestion.

[...]

Thanks for the info. Any reply will be in rec.amateur.homebrew.

Just say here that I found a stepper motor forum and someone wanted a similar solution, ie to drive a 12v bipolar stepper. I went to: http://us.st.com/stonline/index.shtml where I typed in L297 and (seperately) bipolar stepper and now have some application notes (L297, L298, L293E). However, on first perusal I wonder whether they are too sophisticed for my needs. I'm wanting this stepper I got to drive a variable capacitor 180 degrees backwards and frwards, not to make a floppy disk drive work. And I'll need some indiction of where the vc setting is at I suppose. Seems I would need micropossor control with the L298, L297. Do I need that!!

"...Scotts valley CA, DC12v 1.0A/ï¿½ 1.32 Ohms 400S/R. Out are 4 wires, red, blue, white and yellow...."

This stepper I have is bipolar, it's got 2 coils. This is what I get from the markings: Working voltage of coils :12v; Working current per phase:1.0A (presumably " /ï¿½" means per phase). Coils' resistance: 1.32 ohms. I think 400s/r will mean 400 steps per revolution. That means it's a 0.9 degree

motor.

(I'm off to look at this stepper forum :

Http://www.eio.com/public/stepper/)

Rich.

Rich,

Download program ENDFEED from website below. Takes only a few seconds. Not zipped up. Run immediately.

From given antenna and ground height and length dimensions the program computes radiating efficiency of any vertical or inverted-L at any frequency.

Also micro-henry and picofarad component values of L-match and T-match networks to match the 50-ohm transceiver impedance.

To wind your coils on empty toilet-paper tubes with 18 gauge wire download program SOLNOID2.

Get a ULN2813 or ECG2018. 8-Darlington-pair IC capable of 600mA each output, more than enough for typical disk drive steppers or dot matrix printer steppers (good source of nice steppers-cheap-as long as you don't get Panasonic, most of those are 48V I think). TTL or CMOS input. Back-EMF protected. Good for two unipolar four-coil steppers, costs $5 max.

Wire up the common/commons to positive supply, and each coil wire to an output pin. That's it. All you have to do is apply a logic signal to the input terminal across from the output pin you want to activate.

You'll want to make a small logic circuit or PIC to drive the steppers, or use a computer for testing. In that case, use the parallel port pins 2-9 and ground. A simple way to get parallel port stepper controller software is to search for "stepper controller" and "kit" on your favorite web search. I find that many companies are selling parallel port stepper controllers that are no more complicated than the chip above or else a few FETs. A lot of these will operate pin-for-coil like the circuit above. Don't buy their controller for $75, just download their controller software since many of them seem to provide it for free on the internet; supposed to be included with the kit on a floppy. All it does is strobe the parallel port lines in an appropriate manner. Some let you set two-phase, wave, and half-stepping as well as speed and direction. One is usable from DOS batch commands. The actual names escape me at the moment since I don't use them anymore (project moved to PIC control).

This is the most useful information I know about stepper control, hope it helps someone.

Well, unless someone chides me, I'll post on all 3 forums.

I need to establish some performance parameters for this receive only remote-control ATU I want to make.

I envisage this bipolar stepper motor turning a varable capacitor. So it probably needs to reverse direction. Also, I _don't_want to control it from my PC. My minds eye sees pressing a button making the motor go one way, pressing another making it go the opposite way. It must know when it's reached end of travel. I wonder of there is anyway I can know the motors anguler position, so I can set it where I want it. (unless I just tune for peak noise/signal on rx).

Of course I need some hardware to do all this.

If anyone has any suggestions, feel free to suggest anything.

Rich.

I constructed a 1 MHz oscillator and locked it to LORAN. I then compare the phase of the 1 MHz. to 1 MHz. derived from the counter time base. I use a
computer to store readings every 15 seconds and run the program for a few
hours. I can get accuracy of about one part in 10X10 with my setup.

This ain't quite the answer you want, but do a web search for "stepper motor", and in particular look out for the tutorial by Douglas Jones. I've recently been through this mill, and you'll get loads more info from the web than I could be bothered to type in.

Your motor is probably a bi-polar motor, requiring H-bridges to drive it.

Am important PS - if you keep the electronics from whatever eqpt you scrounged the motor, you'll find all the necessary drive electronics!

Hello--
A recent (i.e., 2000) issue of QEX magazine featured a solid-state version plus extensive notes on the technology (and even included a squelck). PC boards are available from FAR Circuits. The design also features an RF stage for isolation.

73--

I've been playing with bi-polar stepper motors here at the house. I've written some code that runs an an Atemel AVR processor to control them.

It can has the following:

1. Can control 2 stepper motors.
2. Has independent toggles for cw/ccw rotation for each motor.
3. Seperate enable pins for each motor.
4. Speed is controlled by a clock signal.

It will interface to some 2955 and some 3055 transistors to sink the current.

If you are interested e-mail me and I can send you the code and specifics on it.

Driver chips for these are readily available. I've
at least one in the junkbox. Yours for the asking.

The logic required to get the driver to activate the
motor in the way you want it to is another problem
which you'll have to read up on.

Thread's only a few hours old and we have an expert
already and no less than 12 replies.

It pleases me to see that, for once, instead of megabytes of
backbiting and insults, genuine technical expertise has been
offered.

There's hope for the newsgroup yet!

Charles Kitchin has been doing work on the superregnerative receiver
(and regen for that matter) in recent years. He's tried to improve
on the basic concept, not just make it transistorized. It used to
be that you could find a superregen receiver in any collection
of solid state circuits, but you don't see them that often, and
they were fairly garden variety.

In the 2001 edition of the ARRL, there is a superregen by Charles
Kitchin, and it's been in the past few editions too. He picked
a good FET, put a grounded gate amplifier ahead of it, and included
control to adjust the waveform of the quenching, which he says
impacts on the circuit operation, particularly in narrow band use.
It doesn't say if this article appeared elsewhere.

He had a circuit for a six meter superregen in QST a few years back,
but I didn't buy the issue since it appeared to be your average
superregen.

He also had an article in Communications Quarterly for Fall 1994.
I've yet to see it, but I imagine it's like his article on regen
receivers in the Fall 1995 issue of the same magazine, where he
goes back to look at the tube-based circuits and origins, and
then provides some solid-state circuits that improve on the art.

I posted something about superregens last year, and I got email
from him later (apparently he didn't have newsgroup access), and
he was going to have an article in QEX in the July/August QEX.
I see further in that message, that he included a list of his
articles on the topic:

"High Performance Regenerative Receiver Design", QEX magazine, Nov/Dec
1998, pp
24-36.

"An Ultra Simple Receiver For 6 Meters", QST magazine, Dec 1997, pp 39-41
American Radio Relay League (ARRL) Publication, 225 Main St. Newington,
CT.
06111

"Super Regeneration: the Lost Technology", Communications Quarterly Fall
1994,
pp 27-40.
The above super regen article is a bit outdated as it was written before I
discovered how to modify the detector to receive NBFM.

I have 140 pieces of a type N panel mount RF connector for sale. These are NEW. They have a square flange that mounts with 4 screws to a panel or bulkhead. The pins have been slightly machined but otherwise the connectors are perfect.

This is what the connector looks like: http://www.rfconnector.com/nsf42xx.htm

I would like $150 U.S. for the lot or the equivalent in Canadian $ or make me an offer.

Thanks, Nick

Bill,

I've been running one of the Motorola UT series GPS cards for a while here. They put out a pretty good 1 pps signal. The setup seems to floor out at 24 hours in the 2-5x10-12 range. I'm not sure if that's the floor of the GPS or the floor of what I'm running it against. Loran would probably work very well here as well. I did the GPS thing since it was cheaper.

Gday all
I am pleased to report that I have finally got the beast to work
As always, the error was mine ( ...sounds of self flagellation)
The data direction register in the micro port driving the DDS was set
to all inputs!!!
Strangely enough it would still drive the DDS board at low data rates
but not at normal speed.

This pseudocode for starting the device in serial mode seems to work

Start Main Clock
RESET high
Wait 10 clock cycles
RESET low
Stop main clock
IORESET high
IORESET low
;serial data
07 ; Address of control reg
00
00
00
00 ; Write all zeros to control reg
Start main clock
Wait 100msec ; Plenty of time for an internal update
; then internal update will be switched off
Stop main clock ; though it doesnt matter now
IORESET high
IORESET low
; serial data
07
**
**
**
** ; whatever control options you want
IOUD high
IOUD low
Start main clock
Write freq word etc to DDS

Thanks to all those who advised (Bob Camp, Stephen Swift and others)

Richard

483. Iterference to 802.11 LAN on 2.4 GHz band - does this ring a bell?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-23 10:50:02 UTC
From: John Miles <jmiles@pop.removethistomailme.net>
Message-ID: <3A6D45D2.1CAB@pop.removethistomailme.net>
Source record: 55280
Cross-posted to: rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew,sci.electronics.design

I've recently been fooling around with some 802.11 wireless Ethernet hardware (Lucent Orinoco) at home. It seems to be working well for the most part, but I've been seeing severe dropouts on a very occasional basis due to the appearance of a fairly-strong interfering signal close to where the Lucent hardware operates. Typically the interfering signal has been popping up late at night (around 1 AM local time) and lasting for only a few minutes before going away. It's not causing any real grief but I'm curious where it's coming from.

Last night, the QRM lasted for quite a while, and I managed to catch the culprit on my SA. I don't have a portable receiver for this band to help track down the signal, but I would be curious if anyone recognizes its spectral footprint and can tell me what kind of device to look for. I haven't run across anything like this before -- it doesn't look much like a microwave oven, and it doesn't look anything like another 802.11 device.

The signal at http://209.95.122.40/jm/qrm.gif seems to consist of an asymmetrical series of decaying sidebands roughly 2.6 MHz wide, starting around 2.4615 GHz and taking up about 10 MHz of space at its -6dB points. What kind of device is doing this, and who do I yell at to make it stop? :)

At the moment I'm looking at bipolar motor drivers, which of course involve the H bridge cicuit.

I've been looking at the L293 Push-Pull Four Channel Driver. You can see a schematic at:

http://www.hvwtech.com/dnload/datasheets/L293d.pdf

Please look at page number 3.

I have some points.

As far as I can rell T's 13, 14, 15, and 16 make up one full H bridge. Ts 27, 28, 28 and 29, make another (note the misdescription in the schematic).

T's 13 and 14, T's 15 and 16, T's 27 and 28, T's 28 and 29 are half H bridges and make one channel, associated with an output. That's why the L293 is called a 4 channel driver.

Now then, concering the output: this will either be positive or to to ground.

Logical inputs in the proper sequence are sent to inputs 1, 2, 3, and 4. The purpose of the chip inhibit connections I know not.

Okay, I was confused by the block diagram on page 1. Of course its a block dagram, but how is one to know that outputs (on pins 3, 6, 11, and 14, will be either +ve or to ground? I was looking for current flow from Vc through the triangles to output, or alternatively current from source (ground) to output. I mean is the output assumed to be Vc or ground?

Please comment if I have misunderstood something.

Rich.

The FCC rules state that part 15 devices may not interfere but also that
they must _accept_ any interference, and this is also printed on the part
15 hardware tag, that appears to be a penalty of operation in the ISM band.

:-(

What channel are on operating on? The receiver responds to +/-8MHz about
the carrier, so Channel 1 at 2400MHz would appear to be unaffected by the
interference. Likewise a higher channel might be safe (802.11 channels
are spaced every 5MHz). How stable is the frequency of the interferring
noise? It's likely a high harmonic of a spike signal... Have you been
able to see any of the other harmonics? This would allow you to calculate
the basic repetition rate, which might provide a clue.

Let us know what you learn.

Thanks,
- Win

My first guess, no-one, as per the FCC part 15 status of the 802.11b device,
it must accept interference, including that which may cause unesired operation, you
know it all.

Look up Seattle wireless to learn how to at least build a directional 2.4 Ghz antenna (I might be tempted to try and borrow an MMDS downconvertor,
an find a portable SA to at least find where it's coming from, than if they have
a licence to transmit there.

Source record: 55290

Does anyone know how to get these filters in small quantities? I was looking for 455 KHz center freq, CW B/W types for a HB project. A search of the Collins web site, even by part number, produced nothing, except a load of frustration... It seems to be geared up to Avionics Systems sales only , definitely not small sales to hams. I seem to remember a product review in QST in recent years, but a search of the index on the ARRL web site came up blank also, maybe it was in QEX?

Any leads would be appreciated,

Dan AC6AO G3NCR

Just a thought: Could the culprit be one of those new 2.4 Ghz Digital, SS
or Non-SS (Spread Spectrum), cordless telephones like some of the models
vended by Panasonic under the GigaRange brand name? SS phones only stay
on any one channel for a little while and try to avoid occupied channels
so that might explain why you only occasionally experience interference
from one of these gizmos. And I believe they share some of the same
frequencies as 802.11, but I'm not sure on this - if they do then they're
a potential culprit.

Sorry that I can't be more help, but I'm looking into 802.11 wireless for
a part of my home LAN and when I spotted your post I just had to but in.

I watch for new postings this thread but I would appreciate it if you'd
email me if you do identify the culprit. Especially if it turns out to be
a 2.4 Ghz cordless phone - I've got one so I'm naturally curious.

The low cost torsional mode miniature filters are less than $100 for one filter.
Good quantity discounts for a group buy are available. They are excellent.

Because the interference occurs at 1 AM, I beleive it is a microwave
data transmission (from a bank or something), if not, probably a
genuine ISM emission
(like weather radar maybe)

499. Calculation of microstrip bandpassfilters

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-23 20:39:44 UTC
From: Peter Bolch <320058850955-0001@t-online.de>
Message-ID: <94kq9vohe00$1@news.t-online.com>
Source record: 55296

Hi

I need some bandpassfilters for a frequency multiplier chain and thought of using two coupled microstrip lambda/4 resonators (one end grounded, taps for the input/output connection).
Can someone here provide hints how to calculate such filters? What is the right location of the taps if input/output impedance, spacing and line width are given? Some rules of thumb will be enough at the moment.

Peter

500. Gel type lead acid battery re-vitalisation

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-23 20:41:42 UTC
From: Frank Dinger <gm0csz.kn6wh@invertain.freeserve.co.uk>
Message-ID: <94l1gddpu1@news7.svr.pol.co.uk>
Source record: 55200

Some time ago I read a bulletin (in one of the amateur radio news groups) about the possible re-vitalisation of sealed lead acid batteries. Although sealed , they have a built-in pressure relief facility .
When the complete unit is heated-up ,say in hot water (leaving the connecting lugs dry), and subsequently allowing the battery to cool ,while keeping some (distilled) water droplets near the relief valve area ,some of that water would be sucked inside restoring the battery's ability to be charged.

Has anybody on this newsgroup actually done this , and .....with positive result ?.

TIA for any info on this topic from any 'practitioners'.

73 Frank gm0csz.kn6wh@ukrs.org

> These are new batteries that I am using.
> I thought I might be over charging them, but I am not.
> Tell me what I am doing wrong.
> Give me a solution.
> I would like to counties to use this set-up if possible, because I have
> it placed neatly in my shack.
==========
1) Safety : If car battery is not hermetically sealed , watch out for a
potentially explosive gas mixture of
Hydrogen + Oxygen in your shack . Non-hermetically sealed batteries
should be kept in a well ventilated
area

2) Car batteries are not the most appropriate type of lead acid battery for
back-up .
It is better to use deep cycle batteries also known as leisure batteries
as used in RVs and for camping.

3) Not knowing up to which voltage your car battery-in-the-shack is charged
, perhaps 13.8 V. , it is important that when a non-sealed battery ,it is
charged to 14.5 V for a couple of hours before being put back on 13.8V
charge voltage, approx once every 2 months ,.

4) If not hermetically sealed ,check electrolyte level approx every 2 months
, if too low add distilled - or de-ionised water.

5) To stay healthy a battery on back-up duty needs 'exercise' , hence once
every 2 months discharge it to 11.5 Volts , immediately followed by
re-charging.
Especially this activity I found very rewarding.

I use 4* 75Ah leisure batteries for my station (100W HF rig ,TNC , 25W VHF
transceiver ,test equipment and operating desk lighting and experienced
loss of battery capacity after several months on charge by a 2 Amperes
charger at 13.8 V . Following a discharge to 11.5 V (battery fully
discharged ,although some say it should be as low as 11 V) the batteries
have regained their full capacity ,demonstrated by higher operating voltage
at max current draw during 100W CW + SSB operation.
I now stick to the above 2 monthly routines interleaving the
discharge/recharge/toppping -up with the short-term higher voltage charge
operation.
The discharge operation is performed on 1 battery at the time .

In the shack I also have a few hermetically sealed (gel type)batteries which are normally connected to the main header ,kept at 13.75 V ,however during the short period of charging the main batteries to 14.5 V , the hermetically sealed batteries are disconnected for fear of loss of capacity resulting from ultimate electrolyte starvation (since they cannot be readily topped -up)
These batteries can be connected in series when the temporary need for a higher supply voltage arises ,for example when testing up to 60V circuits (5 gel type batteries in series)

Each battery has its individual (nearby) fuse for obvious safety reasons.

In the next few months all of the above batteries will be charged by a wind generator + 2 solar panels .

Hello--
I've been looking for some of these for Steve Hageman's "Personal Network Analyzer" project (Jan.-Feb. 1998 QST), but no soap.

I'll attempt to use NE625s or SA627s (unsure of the exact part numbers-- they're not handy as I write) that are available from Radio SHack-- these appear to include the IF and RSSI innards of the 604 but with an added mixer. The pinout of the IF section comes close to matching the 604, but the front four and two rear pins need to be spread out (dead-bug style) and suitably bypassed or otherwise terminated.

If all you need is an RSSI/logarithmically-scaled detector, take a look at Analog Devices' Llog amp devices (e.g., the AD8307). This chip costs approx. $15.00.

Good luck, and 73--
Brad AA1IP

John Miles wrote:
<snip>

I'm pretty sure it's not an oven, because it's a relatively stable signal. (At least in the shot I took, that is. I didn't think to zoom down on one of the lobes.)

I just took a picture of the Panasonic 1100W microwave in my kitchen, at http://209.95.122.40/jm/uwave.gif. If you look closely you can see my 802.11 signal foundering in the swamp of garbage from the microwave, at around 45 dB below the oven noise.

(Fun factoid of the day: the microwave and the 802.11 access point are both located about the same distance -- 30 feet or so -- from my workbench. This suggests that you'll get about 10,000 times the RF exposure standing next to a microwave oven, than you would from an 802.11-equipped laptop. :) I didn't think ovens leaked that much.)

Win's suggestion of an impulse-noise harmonic seems intriguing -- J.C. Bose successfully ran a spark gap transmitter at 60 GHz in 1905, so I guess anything's possible. But it sure looks like some kind of band-limited DSSS signal to me. A periodic data dump from a nearby bank or store could make sense; there's a lot of commercial/retail property on my block.

The main lobe's width suggests a data clock rate of around 1.5 Mbps if I understand the theory correctly, which seems like a common-enough data rate (DS1 telephony, SP/DIF audio, etc.) However, the book I have suggests the side lobes should be half the main lobe's width, while they appear more like 80-90% as wide in the shot I took.

At any rate, the 802.11 access point is using channel 10 by default, so it looks like I could miss the interference easily enough by dropping down a few channels. It'd still be interesting to figure out what's going on, though. I wrote some waterfall-display code a couple of years ago and it's still lying around here somewhere... when I get some spare time I'll hook it up to the GPIB card and do a 24-hour survey of the whole band.

Will post the results if I find the source. Thanks for the input, it's appreciated!

In fact I have dispensed with the main clock control and it does not
appear to corrupt the serial data - ie the part updates itself during
a serial write cycle without interrupting the serial transfer.
Presumably it updates garbage and then the proper data so I suppose
you might get odd outputs during the serial transfer.

Richard

Glad I could contribute, even though it wasn't much. I love this part
because it will do everything I want along with everything my customers
want. Unfortunately, my board is too pricey for homebrew. I wish
I could figure a way to make it cheaper (besides making 10,000 of them).

Great to see it working for you.

Thanks for posting the psuedo code-- looks good.

Steve.

Richard,

The only time I can see the internal update being a problem is during a frequency change. You *might* put out a couple of cycles at a weird frequency if your serial clock was slow relative to your output frequency.

In an application that uses filtering after the DDS I doubt you would have any problem at all. If you run the output into a phase detector this could drive it a bit nuts.

Enjoy!

I looked into doing this, but found that locking to the LORAN C signal
was not so simple. I thought there was no continuous carrier. Was this
wrong?

How did you do this? The NIST Time and Frequency Measurement group
indicates that the LORAN signal is the most stable signal available to
all of us, except perhaps for the 60 kHz WWVB signal.

Good idea - one that I've thought of trying, but have been put off by having to run a seperate control cable to the box... I'm still watching with interest though...

> Stepper motors are easily obtainable and
> cheap (from old floppies).

If you need more torque (say, for a transmitting ATU?), try looking in scrap printers or fax machines, they're riddled with steppers! (I have a collection of about 30 steppers, one day I'll get to use them, I hope!)

> I've got stepper motor in front of me now, is there any way

I'd guess that "400 S/R" probably means "400 steps per revolution"?

Have you looked on the 'net? There are several "stepper motor" groups which are quite useful :-

http://www.eio.com/stepindx.htm
http://www.doc.ic.ac.uk/~ih/doc/stepper/
http://www.st.com/stonline/books/ascii/docs/1679.htm

(The last one is an Application Note on bipolar motors from SGS Thomson)

OK, what about an inductor in there as well? It shouldn't be too
difficult to fabricate a roller inductor for RX only.

> So it probably needs to reverse direction.

Yup, that's easy electronically. (Bipolars included?)

> Also, I _don't_want to control it from
> my PC.

Go on! Why not? the cheapest of cheap PC's could do it, and it would
save a *lot* of hardware manufacture!

> My minds eye sees pressing a button making the motor go one way,
> pressing another making it go the opposite way. It must know when it's
> reached end of travel.

Why? you don't need to with the capacitor (if you use an 'endless'
capactor).

> I wonder of there is anyway I can know the motors
> anguler position, so I can set it where I want it.

How many steps have you taken from point 'X', that's your current
position.

> (unless I just tune for peak noise/signal on rx).

Probably this is just as easy, but you lose the "resetability" you asked
for :-(

> Of course I need some hardware to do all this.

Old/scrap Fax machines and printers - they are gold mines for gears,
sprockets, optical coding discs, belts, cams, springs, bearings, etc.
They can also provide the electrical components - microswitches, optical
sensors, driver chips, solenoids - the list is almost endless.

> If anyone has any suggestions, feel free to suggest anything.

I remember the remote tuning network at our local radio station in
the old days. Ol' Sparky rigged up a couple of antenna rotors
with the controls mounted on an inside panel to drive the big
variable caps out in the "hut". Overkill, but it worked.

Hi
I am looking for any information regarding the generation of
quadrature signals.

It needs to be wideband, i e 20-140 MHz or so...
Using all-pass filters seems to be a viable way, but where do I find
any design information. Searching the internet reveals several sources
but they are old, very old, hard to find!

If you have any information please post it here

Thanks

Intuitively I'd be thinking of:
(a) a digital source using a multiphase clock, or
(b) a VCO pair with different types of phase detector. The latter
work at different phase angles depending on their type. That way the
reference osc and divider data can at least be common.

Just ideas.

Thanks for the information!
I'll try to find the QEX, we did start subscribing 95.....

Apparently a ham, Robert Dome W2WAM, did pioneer the phase-difference networks.... but where can I find his work? One reference is Electronics Dec 1946! Anyone not recycling magazines??

Using PLL and other similar ccks are not viabel. The component will be used in a butler matrix (direction finding) with multiple input signals.

Cheers

Lasse

I have just managed to get a signal from the AD9854 quadrature direct digital ynthesizer on a prototype board. If you want a LO signal, this chip might be a possibility. Admittedly the spur output might be unacceptabvle for many applications. The chip will produce an accurate pair of quadrature signals, closely matched in amplitude and phase. Using an image, you could reach 140MHz. The device will cover to 70-80 MHz without a problem.

Ah Yes! The Dome phase shift networks. Others in the field were W2WZR, K2QCX, W1DAX and Jim Kohler, VE5FP/VK2BOX. I don't know whether these are even still alive but you might try their call book address for more information.

Richard, when you get that thing percolating,0-80 MHz. I want to buy one. Complete with whatever you finally get to make the thing initialize.

It's so easy to forget your local library!
After spending several hours searching the web I took a reference list with me to our library. It sure was a pleasant surprise! Four articles from -49 -60 were immediately available, and Electronics -46 should be available tomorrow! Even our old Ham Radio was still available.

Honestly I had forgotten how FUN it can be to surf the shelves, smelling the books and just flipping pages. Looking at pictures/ads from an era long before me, noticing familar names and so on can be just as exciting as the new issue of Playboy (yep I am a wierdo).

Hmm, I getting lost in memoires, getting old. Now time for some reading

Ok it wasn't easy but then it wasn't too hard either.
I started with a 1 MHz oscillator and divide it down to the pulse rate
of
the LORAN signal. I generate a short pulse at that rate and use the
pulse
in a sample and hold circuit to sample the LORAN during the first part
of the pulse. The analog output of the hold circuit is used to steer the
frequency of the 1 MHz. oscillator.

To align the sample on the pulse, I trigger a scope with the pulse and
look
at the LORAN signal. I the adjust the divider until the pulses line up
and then
reset the divider to its correct setting. I have thumb switches to set
the
divide ratio.

Hope that helps explain what I did.

My next project is to build a receiver for WWVB on 60 KHz. I would
recommend that that signal (or GPS) be used for any new projects.

John, the conventional wisdom is that a microwave oven operating on
FULL is actually on a 50% duty cycle at 60Hz, i.e. powered on half
cycles only. 802.11 modems are supposed to sucessfully sneak their
packets through undisturbed during the quiet 8ms periods. The MAC
chip should make automatic retries until finding the quiet interval.
What have been your observations about this?

BTW, I like the 7470A plotter emulator software, we'd you get it?

Thanks,
- Win

Anyone know what the values of the oscillator padding capacitors are for all the ranges of this receiver please? I have one to repair and someone has been at the coil pack!

I have a full manual, but the coil pack is only shown as a complete unit, and no values are given for the padders. Appreciate any help that you can give. Thanks brianberry@btinternet.com

525. Radio Shack ME-11 DMM serial cable info needed

Charlie,
See if you can get your hands on The giant book of electronic projects. It has a schematic and parts list for a low power AM transmitter and you can use the ocilator section of the cw tansmitter kit section to send CW. Good luck. C U on the bands.KB2YFP

Jim,
if I recall correctly this was used by the AEG/Telefunkten E-series
receivers for HF.

Splitting the rf in two paths would reduce the signal level by 3 dB
and thus improving the IMD by 6 dB. Since the splitting/summing
network was consitiuted of 90 degree hybrids I guess the greatest
advantage would be cancellation of reflected and unwanted signals back
into the mixer.

Good Luck with the experiments

> What have been your observations about this?

I can still surf the web OK with the microwave on, but LANEVAL reports zero throughput for some reason. Maybe it tries to keep the wire saturated without backing off to allow the necessary retries... dunno.

There's an option in the Orinoco client software for "interference robustness" that's specifically intended to deal with oven interference. It evidently breaks the packets up into smaller fragments that are more likely to fit into the quiet half-cycle periods. It doesn't seem to help LANEVAL, although I didn't try enabling it at both the client card and access point.

> BTW, I like the 7470A plotter emulator software, we'd you get it?

Thanks! I wrote it to parse the output from my Tek 494P's PLOT? command. That's a fairly-old instrument (Reagan-era eBay special), and it only uses a few basic HPGL commands that were easy to reverse-engineer by looking at a sample plot file. You're welcome to the C source, but it's not likely to work with any instruments besides the 49x analyzers yet.

If I can find a reference for the 7470A somewhere, I'll try to bring the emulator up to date with all of the HPGL commands from that generation. I'd like to use it with my 2430A scope too, but its HPGL output looks much harder to reverse-engineer than the 494's. Font support is going to be a PIA in either case because my (also homebrew) graphics library doesn't do scalable fonts. I'll probably have to switch over to GDI if I go much further with it.

You may want to get this software package ($10 US). I had this bookmarked, but I have not use this program before. The snippet below is from the web page. I think this will do want you want, and then some.

"PUFF is a program for laying out and analyzing microstrip and stripline circuits on IBM-compatible personal computers. The program is fast and easy to use. Circuits are laid out on the screen using cursor keys, and may be analyzed for scattering parameters in the frequency domain, or impulse and step responses in the time domain. PUFF's element library includes several lumped elements, transmission lines, and coupled lines. Multiport scattering parameter files may be read into the program to represent transistors, to create hypothetical components, or to compare theory and experiment. PUFF also produces photographic artwork on dot-matrix and HP LaserJet printers. Support for VGA, EGA and CGA graphics is included."

FYI, I've uploaded the current version of my HPGL plotter emulator to http://www.qsl.net/ke5fx, with full source.

It will probably take some effort to get it working with anything but the Tek 492/494/495/496/497 analyzers, but it ought to be better than nothing as a starting platform. I'll add vector fonts to it as soon as I can find an HPGL reference of some kind. Suggestions are always welcome....

532. Connecting radios together 'back-to-back'

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-25 03:28:22 UTC
From: David Baker <david@baker.pc.my>
Message-ID: <g67v6t8f7hehmff78nmmo5amnm4phq6qf1@4ax.com>
Source record: 55229

(Sorry if this isn't strictly amateur! I'm having trouble finding a more suitable newsgroup to post into...)

I have 2 radio transceivers (Pacific Crest RFM96W - http://www.paccrst.com/FTP/anon/Intl.rfm96w.pdf) that I want to connect together by coax. I need to do this as if I try using the antennas for my testing I get all sorts of reflections & interference due to the small size of my concrete & steel workshop.

I can remember from the dim dark past during my Air Force days that I will need an inline attenuator to cut down the signal so as to not blow the front end out of the receiver. However the theory has long since been erased from my memory banks & I have been unsuccessful trying to find out what I need.

My radio transmitter is 2 watts. My radio receiver has -117dBm sensitivity. Frequency is 450 MHz (approx)

Anyone know how I can calculate the attenuation required?

Now for the tricky bit - how do I make an attenuator with the above value? Is it just a resistor? I can see from the following website:
http://hometown.aol.com/arrow146/atten.html
that they use what appear to be only resistors. As I don't need anything with variable attenuation (for the moment), I'm hoping I can do with just one or 2 resistors. Would some kind soul please let me know if this is possible, and if so:

What value resistor(s)
What power rating
What composition resistors

Thanks in advance,

Dave

I might be possible to mix your signal up to a frequency where the required bandwidth is possible with a 90 degree hybrid and then mix both the in-phase and 90 degree signals down to the original frequency. Look at some of the Mini-Circuits stuff at http://www.minicircuits.com/dg02-102.pdf .

I once built a quadrature splitt that worked from 1 to 140 MHz. It was simply a constant resistance all pass network in the half lattice configuration using a center tapped transformer. The lattice arms had series resonant tanks in series with parallel resonant tanks. The pole and zero frequencies were calculated using an IEEE paper by Lankershim and Shirley (I think it was in the 1960's, or 1970's in Trans. on Circuit Theory). This is the best of many papers on the subject, IMHO. I am not aware of any recent papers on the subject; I think everything that could be said about was said about it 30 years ago. You should be able to search the IEEE web site and find the citation. The component tolerances are not critical for these networks. I used ordinary molded inductors and ceramic caps.

Rick,
I have been going thru all IEEE Trans. Ckt Theory 63-79 and found nil
from Lankershim and Shirley. I even tried IRE 60-62 with similar
information.

But I am not sure it would be suitable to use RC network as this would
present quite high insertion losses.

I do have an article "Normalized Design of 90 degree Phase-Difference
Networks" by Bedrosian from IRE Trans. on Circuit Theory june 1960
that seems promising!

Cheers
/Lasse SM5GLC

I have an internal 100MB ZIP drive that has apparently started to have seek problems -- when running Norton Disk Doctor, the surface check regularly fails around the middle of the disk, and I can hear the head assembly repeatedly clicking as it retries.

I've tried several disks, some fresh, some old, and all exhibit the same problem, so I'm certain it isn't the media.

Unfortunately the drive is held in place by screws that are very difficult to get at, so before I completely disassemble the computer, is there anything else I can do to identify/fix the problem with the drive in situ (e.g. cleaning)?

Lasse
I have tried the "polyphase" network at audio and RF up to 30 MHz.
This is a RC network in a ring configuration. At audio it is driven
using opamps and at RF with ferrite transformers. (the network should
be driven by push pull signals). You can achieve a couple of decades
bandwidth using multiple poles but it gets quite lossy (>20dB) if you
want reasonable accuracy. You can get 50-60dB sideband suppression at
audio from 200Hz to 8KHz or so using an 8 pole audio network. (this is
equivalent to about 0.1 degree accuracy)
At 30 Mhz the accuracy wasnt too good (around 25dB). I used these
networks as phase shifters for "phasing method" ssb
receivers/generators in the LO and audio sections..

Hello
I had quite he same problems on my own Zip drive.
That's a mechanical fault recognized by IOMEGA,fortunately the
equipment was still under warranty and I got it freely replaced by
IOMEGA in Netherlands.
Good Luck

IOMEGA ZIP Drive "Click of Death" syndrome. Made big news a while back.
Earlier ZIP drives were well known for failing because of this.

> be appreciated.

I bought several. That's a remarkable value. The serial port interface uses a standard serial port cable. I suspect you only need a few of the wires instead of all of them, but I had an old one with all 9 wires in it and it works fine. The software is packaged with the unit, reads the data into the computer or into a file. If you purchase one and are interested, I have a piece of software that will take a reading every second, average it over a minute and put that info into a comma delimited file for later use in a spreadsheet. I find it of value monitoring a VLF station for signal strength, but lots of applications.

There have been numerous designs in the magazines (QST, QEX,
RadCom, etc.) in the last few years for modern analogue
radios. Some were phasing radios, while others used the
3rd method. Look for callsigns KK7B and S53MV to start.

There have been a handful of DSP radios in QST and QEX
(consult the indexes). The DSP stuff is well-covered in
all the usual references. Every such radio I've ever
seen used a DSP eval board...

Sounds like what is known as the Click of Death, which at one time was more
common on early Iomega Zip drives. Try the following lin it may help.

http://www.accesszone.com/clickdeath/index.html

Good advice from Tom. The GRC (Gibson Research Corp.) site is excellent.
If I remember right, the drive may turn out to be OK. It depends. One thing
others did not mention is a free software on the GRC site called "TIP"
(Trouble in Paradise). It will figure out whether the drive or the media are
at fault. The picture does get cloudy, however, if you have both bad media
and a bad drive at the same time. Anyway, read his site. TIP is excellent
and I use it from time to time to check my drive and media. It is well
worth the effort to get it and run it. Takes a while to run, even on the smaller
100M size media, but very informative and definitely worth taking the time
for. 73, David K3KY

John
I am developing a DDS circuit which could be used as the LO of such a
device.
It uses the AD9854 quadrature DDS chip and I am in the process of
writing the software - I expect it will take a few months yet. I have
managed to get a signal from the device so far which appears as a nice
quadrature pair from the 2 outputs.

I don't have a ME-11 but I did pick up a 22-168a from the Shack's bargan table on close out several months ago. When I got it home I found that the supplied software would not work on my pentium lll 750 with win98. I finally located the author of the software and he sent me an updated version which worked great. If anyone has one of these meters and is having a software problem, let me know.

In brief, I have a multi element TV antenna with a amplifier connecting to 4 televisions. The house lot is laid out in such a way that it's very hard to string antennas up with out having them in close proximity to the TV antenna. Cable is not an option. Satellite is possible but would like to keep regular TV antenna.

At Christmas I found a Six Meter rig under the tree.(MFJ 9406 SSB/CW 10 Watts) which my wife gave me. I put up a dipole to try it out and to my surprise it works quite well. With a antenna tuner I have a 1.3:1 SWR.

My wife hasn't stopped yelling at me sense. Every time I key the mike or try out CW the TV's go blank. I have tried a HI PASS filter but that doesn't do much good at all.
My HF rigs cause no problems at all. I do have a good RF ground

WHAT AM I DOING WRONG??? HELP!!!

Any comments and suggestions would be gratefully appreciated.

Thanks

Hello to all,

I am in the process of making a decision about a power supply for my Icom 706 for base use.

I see these Pryamid supplies. I like that they are linear but are they any good for ham use? Or should I just stay with the Astron brand although they are switching supplies?

The Pryamid is much less expensive but that's not always good.

All replies welcome.

Thanks,
Bill

I have a 35 amp Pyramid supply on the bench. It's been a good supply.
I also have an Astron SS-30M switching supply on the rig. No RFI
detected unless I lay the antenna right on the supply. Astron also
makes linear supplies (RS, RM, and VS series). So does MFJ and Alinco.

Yeah, percussive maintenance.

But seriously, sounds seriously fscked to me. In or out of situ, I
doubt you'll be able to do anything about it, unless it's still within
warranty.

I had one fail on a machine at work. (wasn't aware this was a common problem,
but what's described is exactly what happened to ours) The computer was
neither a Mac nor a PC; it was a Chyron TV title generator. (Motorola
68040, I think the OS is called "PSOS". SCSI interface.)

Anybody using broadband antenna amplifiers are just asking for
trouble. If it has a frequency response something like 47 .. 860 MHz,
then there is no wonder that it is going to saturate :-).

Are you absolutely sure you need amplification for VHF channels ?
Wouldn't it be sufficient to put a UHF only amplifier directly after
the UHF antenna and just use a passive summing network to connect the
VHF antenna into the downlead ?

If this is not possible, but Band I is not needed (channels 2 .. 6 in
the USA), put a high pass filter around 150 MHz immediately in front
of the preamplifier.

If Band I channels are required, put a 50 MHz notch filter immediately
in front of the amplifier and make sure the amplifier has a good
metallic cabinet so that your transmitted signal does not go directly
into the amplifier.

Here is a link that explains why the interference is probably NOT due to microwave ovens:
http://www.cts.com/browse/solectek/tech-center/tt-microwave.html

I couldn't find a link, but I have seen an article explaining why you should not use 802.11 around fluorescent lights due to interference problems. You might want to explore this possibility (especially if you have a bad ballast).

Thanks David. I downloaded TIP and tried to run it, but it doesn't
support my type of drive. However, as the machine has never been
connected to the Internet, I doubt it has anything to do with Click of
Death.

The more likely cause of the problem is that I recently got into the
habit of leaving the ZIP cartridge in place during power-down and power-
up. I discovered when reading the ZIP drive manual yesterday that I'm
not supposed to do this. So, as the drive is several years old and well
out of warranty, I'm going to have to bite the bullet and buy a new one.

Peter,
many many years ago, there was a basic program for designing slabline filters. I might have it still but on 5 inch diskette but no drive!! I might find a listing of the program if you want. The performance was great I did design a 6 pole 560 MHz filter with 3 MHz BW and excellent agreement both passband and IL.

If you want the "real" stuff try MFilter from http://www.eagleware.com slick easy but expensive.

Good Luck
/Lasse SM5GLC

immediately
> in front of the amplifier .....

You can make a good inexpensive notch filter by placing a 1/4 wave (on your 6M operating frequency) long piece of coax, shorted on the far end, across the input to the amplifier.

573. Re: Wide band 90 degrees phase shift

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-26 13:55:02 UTC
From: Richard Karlquist <rick@area.com>
Message-ID: <Wkfc6.9628$R5.514720@news1.frmt1.sfba.home.com>
Source record: 55168

My network was "lossless" with all L's and C's, no R's. Actual loss with ordinary coils
was a few dB.

CORRECTION: the authors I cited should have been "Albershim and Shirley" (not Lankershim).
Check IEEE Circuit Theory and also Proceedings of IEEE.

Here is a brief description of the circuit (ASCII artwork in Courier font follows):

transformer:
1.414:1 turns ratio
center tap grounded

```
-------)|(---------------------------A-----------------------------------
output X
)|( | |
)|( ------C--------------------------- |
)|(---ground | |
)|( ------------------------B----------|----
)|( | |
-------)|(---------------------------D-----------------------------------
output Y
```

The two outputs, X and Y are versus ground. The input is to the transformer primary.

A, B, C, and D are two terminal LC networks. A and B are dual networks and C and D are dual networks. Furthermore, A and B are chosen to result in a constant resistance all pass function to output X and C and D are chosen to result in a constant resistance all pass function to output Y. Many network theory books describe the constant resistance network; basically, the geometric
mean of the arm immitances is equal to the termination impedance times a constant,
typically 1/4 or 1 or 4.

Operation is as follows: suppose A is a parallel resonant tank at 1 MHz and B is a
series resonant tank at 1 MHz. at low frequencies. At low frequencies, the network is a straight through (no phase shift) to output X because A is a short
circuit and B is an open circuit. At 1 MHz, A is an open circuit and B is a short circuit, so the network is a 180 degree phase inverter. At high frequencies,

A is again a short circuit and B is again an open circuit so the network is again
a straight through, no phase shift.

It turns out that the phase shift around 1 MHz is extremely linear versus frequency.

Now suppose C and D are arranged in a similar way to drive output Y. Again, output
Y will have a linear phase shift versus frequency. But suppose we use a different
frequency than 1 MHz for C and D. It turns out that we will still get a linear
phase slope versus frequency, but if the resonant frequency is chosen correctly,
it will be 90 degrees advanced or retarded from output X.

Thus, over an octave or so, you will have a quadrature network. The frequency
response can be extended without limit by adding additional resonators in the arms
so that the A,B resonant frequencies are interleaved with the C,D resonant frequencies.

I believe 3 tanks per arm will get you 20-140 MHz. As I said, I built one from 1-140
MHz that really worked, and it was easy.

What good will that do ? I thought a 1/4 wave translated a short to an open.

OPEN on the far end!

Best use a piece of 'large' coax. I've used 3/4" cable TV hardline.
It's notch is wide enough that you should cut it low in freq. to keep
from killing any TV2 signal. Cut it for 49 - maybe 48 mcs --- you
can always cut long coax shorter, but you can't cut short coax longer.

Make that 1/2 wave and you might see a notch :-) on that frequency
(and remembering to compensate for the velocity factor) if you are
using shorted stubs.

A 1/4 wave _open_ stub could also be used, but it is harder to tune.

Hello Francesco,

I'm not really to sure what your asking... you need to be more specific
about what you want to do.

Do you want to change to the oppisite side band of a radio you now have..?
Do you want to add the sideband mode to a radio, now without side band..?
Do you want to convert some frequency side band radio to another..?

let use know more detail and we'll try to help.

At least one "commercial" oven I turned into a plasma excitor was full wave rectified. I'm sure because the filter caps and linear regulator I added had very limited margin. The oven was just a little beefier like you might find in a vending area, Amana I think.

No doubt what you describe is the norm, but it could be kind of ugly on the power factor if a Motel hooked all their microwaves on the same side of the incoming power circuit ;-)

Buy a new Zip drive. That's what I had to do. Mine was made by
Panasonic and failed after 2 years.

The software which came with the replacement I bought attempts
to solve the problem (mentioned in another post) of leaving
media in the drive, by ejecting the disc when you close down
Windows.

Another problem with leaving discs in the drive is that
Windows '98 will often swop the drive letters around at
random on booting. Particularly if you have two partitions on
the HD, a CD-R/W and a RamDisc. A real pain for the forgetful.
Fixing the drive letters in Device Mananger achieves nothing.

Ooops - I should have said open on the far end - that will cause a low
impedance at the amp input for the 6 meter frequency.

Why ?
I would have thought that cutting coax stubs is as easy / hard for
1/2 wave as it is for a 1/4 wave !!

I ahve used both kinds over the years and have found the Pryamid supplies are ok If you make sure they have the over voltage protection. You just have to rate them about 2/3 what an Astron of the same amp rating. That is if you get an Astron rated for 35 amps, the the Pryamid should be rated for aobut 50 amps. That is for the linear supplies. Have not looked into the switching supplies. I have been using an Astron 50 amp supply for my Icom 706. It is also powering several other rigs and solid state amps for other bands. If you think you need a 30 amp supply then look at a 50 amp one. That way you can allow for expansion.

588. TVI 6 METERS

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-27 00:58:42 UTC
From: "David J. Moge" <n1rzb@mailops.com>
Message-ID: <3a72d6e3@excalibur.gbmtech.net>
Source record: 55192

In brief, I have a multi element TV antenna with a amplifier connecting to 4 televisions. The house lot is laid out in such a way that it's very hard to string antennas up with out having them in close proximity to the TV antenna. Cable is not an option. Satellite is possible but would like to keep regular TV antenna.

At Christmas I found a Six Meter rig under the tree.(MFJ 9406 SSB/CW 10 Watts) which my wife gave me. I put up a dipole to try it out and to my surprise it works quite well. With a antenna tuner I have a 1.3:1 SWR.

My wife hasn't stopped yelling at me sense. Every time I key the mike or try out CW the TV's go blank. I have tried a HI PASS filter but that doesn't do much good at all.
My HF rigs cause no problems at all. I do have a good RF ground

WHAT AM I DOING WRONG??? HELP!!!

Any comments and suggestions would be gratefully appreciated.

Thanks
DAVE, N1RZB

Sticking a needle through the shield and the centre conductor is a
reversible operation, cutting the coax is not a reversible operation.

As I recall it, the roughly 50% duty factor of microwave oven radiation is not
due to half wave rectification, but due to lack of any filter on the rectified
HV supply. The magnetron only fires when the voltage exceeds some fairly high
threshold, so it is quiet near the zero crossings of transformer output.

591. Alinco DR-570T problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-27 03:48:11 UTC
From: KG4FGN <kg4fgn@mindspring.com>
Message-ID: <94th90$un0$1@slb2.atl.mindspring.net>
Source record: 55187

Greetings,

I recently acquired a slightly used Alinco DR-570T. This is a dual band 2m/440 radio with crossband repeater capability. (A hamfest acquisition).

When I use the 2m side, everything works great. When I go to the 440 side, I have problems. I receive great, but when I try to transmit nothing happens (usually). No little bar pops up to show me my transmit strength, nothing. The lights on the display dim a little, but that's about it. Once in a blue moon it will transmit, the strength kicks in to full, but then drops back again. I've tried on high and low power and get the same results.

Weirdly though, the 2m side works great, no problems at all. I've tried two antenna, tried different power settings, etc. No changes, 440 still poops out.

Any ideas?

Thanks and 73's,

Robert / KG4FGN

592. Re: Connecting radios together 'back-to-back'

Newsgroup: rec.radio.amateur.homebrew

Source record: 55188

Your two watt radio has an output of +33 dBm while your receiver has an input sensitivity of -117 dBm, a spread of 150 dB. Your receiver can probably tolerate a fair amount of input level , before it generates intermodulation, say about 60 dB above -117 dBm or -57 dBm, to be on the safe side I would assume about 10 dB more isolation or -67 dBm. -67 to +33 is still about 100 dB of attenuation needed.

Building attenuators is tricky and requires that you use non-inductive, carbon composition resisitors. The amount of attenuation you need is beyond a homebrew attenuator. The leakage across the components at 450 MHz will likely cancel the attenuation you are seeking. Your attenuator must also be able to handle the power of your transmitter (2 watts).

I would suggest a couple of options:

1 That you purchase a 50 ohm dummy load for the transmitter, one signal sampler (RFA-4059-A from Tessco, pn 13503 $61.43 each). (These samplers are adjustable from 20 to 80 dB.) and an inline attenuator for the receiver, something in the 30 DB range. The signal sampling port would be connected via the 30 dB attenuator to the receiver. The attenuator would lower the signal and provide a good match to the receiver.

2. Purchase two attenuators in the 30 DB range and place a switchable "Kay" attenuator between the two attenuators. Use double shielded cable for best results. There are construction articles for Kay type attenuators, however they require a lot of mechanical considerations to shield the sections.

3. In practice, I have simply put a dummy load on each device and positioned them for best operation. Normally FM receivers are not at all sensitive to the signal level above a certain threshold, and the direct signal is likely to be greater than a reflected signal in this configuration. But it sounds like you are looking for better repeatability. In some cases, the receiving radio might need to be placed in a screen room and the signal coupled through a port in a controlled manner. Without a screen room, you may find that the cable leakage, upsets the signal attenuation.

I hope this helps.

Very easy to tune if you cut the length somwhat short and then put a
trimmer across the end. An alternative is to cut it a bit over length,
remove the outer sheath over a couple of inches and then push the
copper braid back until the line tunes where you need it.

Hi

Cutting a stub to the correct length is like playing Russian roulette.
The alternative is to cut the stub shorter than the calculated length
either quarter or half wave and use a small trimmer capacitor. Use one on
the input to the Amp and one on the out put as well. My experience
suggest that most on the damage occurs in the TV set mixer.
you can locate a stub if necessary at the TV set as well. I have had a
good results with co ax and trimmer it is very easy tune. After a while
you can simply guess the length of coax and tune the trimmer.

598. Re: Wide band 90 degrees phase shift

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-27 18:17:25 UTC
From: Lasse Moell <lasse.moell@please.no.spam.swipnet.se>
Message-ID: <nf367tcg2b5sbv088tp9qe8nri4o433peq@4ax.com>
Source record: 55194

Gee thanks for the information!
I will look up the article and see what I can learn.
So far I dug up 3 interesting articles along with others with minor
useful information:
"Realization of a Constant Phase Difference" by Sidney Darlington,
Bell systems technical Journal 1950

"Normalized Design of 90 degree Phase-Difference Networks"
by S D Bedrosian, IRE Transactions on Circuit Theory 1960

and finally
"Formation of Passive Lumped Constant 90-Degree Pahse-Difference
networks" R B Wilds, Ham Radio 1979

Wildes present usable tables for desingning all-pass networks and it
is simple to de-normalize for any impedance or frequency range.

The other two are having a ball with Cauer Chebychef polynoms which
slightly obscure my need for a simple design ;-))

I have to try some computer simulations to see what can be done and
how sensitive the circuits are for component variations.

This will be a fun project I am sure!

Thanks guys for all the help!
Cheers
Lasse SM5GLC

Hello,
I was having a root round in the shed I have come across an abandoned project - it is a Pye Westminster, I have no longer got information on Westminster's and this is a "special" set ie it is not a W15FM the set is not a Whitehall before you all jump on that it is FM only has 10 Tx and 6 Rx channels I think it is most likely half of a 2 rig set up and is remote controlled.

It is longer than a W15 by 4 or 5 inches (100 - 125mm), the standard PA strip has the final transistor stage missing and in the extra space at the back of the rig is an add on amplifier stage (High power I think maybe 25 watts or more) and a "current limiter" PCB.

The ID plate has the following markings
Cat N° AT90148
Ser N° 81493
Code BL01 VEEX

from the code number I remember it to be
"V" spec IF filters (25Khz)
"E" band Tx (68 - 88 MHz)
"E" band Rx (68 - 88 MHz)
I do not know what the "X" means
Can any one identify what this rig is and more importantly has any one got details or circuit details. I am looking to use the PA for 50 Mhz on my FT690
so any help much appreciated.

Thanks Martin G1GYC

Gentlemen:

W4PQW, Harold, received a copy of the project from the Sixteenth Edition of "Radio Handbook" from William I. Orr. I received permission from Mr. Orr to copy and distribute this.

I have scanned in the project, and have a copy of the electronic mail permission from Mr. Orr on a page I just built for the purpose of distributing this information. I saw your requests in the newsgroup and built this.

http://members.home.net/rbethman/813s.html

You'll find the info at the above site. While it is not a single band amplifier, it shouldn't be too difficult to place it on 160 mtrs.

Enjoy!

This instrument is in fair physical condition. There is some sticker residue on the panel and enclosure. I checked it against another voltmeter and it's working fine. The back panel has buffered AC and DC outputs to drive a chart recorder or other instrumentation.

Besides Signature analysis, this multimeter will measure frequency up to 50 mHz, time intervals up to 100 s, totalize up to 99999 counts, DC voltage up to +/- 250 VDC, differential voltage, peak voltage, and resistance measurements. This instrument is in excellent cosmetic and functional condition, with the exception that one of the little probe clips from the measurement pod isn't working properly. They are a semi disposable item, and easily unplug from the test lead. I have used this multimeter to measure frequency, voltage, and resistance, and it's working very well. It is very accurate, most rages have 4 1/2 digits precision. This instrument has an HPIB interface for computerized testing applications. I am including the original operators and service manuals.

Last one of those I saw was back in 1970's and it was a W30AM. The valve at the back was a quick heat PA with a TX invertor on the centre section. I linked one up many years ago and used it on 2M but invertor whine used to be a big problem on mobile use.

I have the manual somewhere in the loft if you're serious about it.

Probably has a label on the hinged cover which says "10TR6" and either A
or B (though I can't remember which was which). I had a pair of these
and modified both to full ten channel operation. If we're lucky someone
will explain how they were used with a twin control box labelled
"PLATOON" and "BATTALION".

>It is longer than a W15 by 4 or 5 inches (100 - 125mm), the standard

W25FM I think was the designation.

Ten channel.

>Can any one identify what this rig is and more importantly has any one got
>details or circuit details. I am looking to use the PA for 50 Mhz on my
>FT690
>so any help much appreciated.

Ah. Well I was going to say "treat it as a W15FM until the last stage,
then follow your nose for the PA". What I almost certainly don't have
is details of the PA stage. If it still has the original crystals and
you have the right equipment you should at least be able to get an idea

of the drive level and thus the feasibility of using with your FT690.

One thing to bear in mind: there's no particular reason why the PA should be linear in its original application so be prepared for that as well as adding turns to coils or whatever to bring it down to 50MHz.

If you can identify the final PA transistors that might offer a better route to getting a suitable circuit.

Dan

Message-ID: <UDPOGEApwyc6EwSd@ddwyer.demon.co.uk>
Source record: 55104

The two major nonlinearities in crystal filter crystals are at the two
extremes of applied signal level.
Crystal dissipation of 0.1mw to 10mw the frequency will move frequency
thus imparting a phase shift to a cw signal, frequency change for a 10.7
MHz could be of the order of 10 to 20 ppm.
If the filter has a loss of 3db then 10mw entering the filter will give
rise to 5mw dissipated in the output load resistance.
At the other end of the level range nW? the crystals may exibit
discontinuous loss resistance/level it is this characteristic caused by
contamination that give rise to "sleepy " crystals that prevent an
oscillator form starting their eq series resistance may be 50R at 100uw
but increase to 150r at thermal noise levels.
Both mechanisms will give rise to intermod problems and filter
manufacturers is properly payed will design and test filters to neet
intermod specs.

Source record: 55106

Hi all,

I'm looking for an op-amp with an output capability of about an amp.
Nothing critical (well, needs to run on 12V), probably a TO-220
package, and cheaper is better. The LM1875 looks good but too
expensive and it needs 16V. Thanks for any ideas.

73,
Mike, KK6GM

Source record: 55108

Hi Dave. I have similar troubles on all the HF bands as well as 6m. My G5RV is about 10' above and 10' lateral to my tv antenna and even with low AND high pass filters, I still cause TVI. I've decided that the antennas are just too close plus, one of the tv ant elements is gone so who knows on which frequencies it is now resonant!? Next I'm gonna try recabling the tv ant with coax instead of twin lead, get a new tv ant, and move the G5RV as much as I'm able. So, while I'm not much help to you, I can sympathize with the frustration of all involved. At least the neighbors aren't complaining! GL and 73.

Have had at over a douzen W15FM for different bands to experiments with, also a douzen F30FM - with R17FM, and R18FM receiver, a T100MN transmitter, an AM25-B, AM25T Vanguard (converted to FM) buying boards from B. Bamber, and some Cambridge FM10d's

Tried to convert it to 6m, but the problem is that - if you increase the capacitance across the coils on the exciter it will be rather sharp tuned and will only cover few channels. Nominal RF o/p from the exciter is 0.15W, not sure if this applies to your version

have much experience using F30FM, and the most important to start with is to add ground connection on as many points on the different pcbs as possible, also using ground lugs on fastening 6BA screws. This even improved modulation with the T30FM transmitter

The T30FM wouldn't give more than 12W, but a simple modification adding few capacitors iimproved this
R18FM may operate fb on 160MHz, but when you try to use it on 2m, it will never be optimum, a BF905 imrpved the squelch setting for 10dB quieting by a figure of 3, you also must add tape under the cover in RF converter.

It is two different versions of W15FM, the first (1967) has bipolar transistors, while the second (1968) has JFET in receiver converter

I never liked the power amplifier in W15FM, it is too old design and can be improved a lot, at least you can obtain far better devices, so for the two metre version (LA3VHF) I used BGY36 power module

I made 5-6 equal TVI filters with two sets of tuned quarterwave lines
using up to 1cm pvc coated wires to adjust the end capacitance.
Notchdepth is 85dB on 144MHz, but they covered most of band III with
minimum attenuation. So I see no reason for this shouldn't work on 6m,
airspaced trimmers may be a good choice, but your suggestion using
needles to short is usually overlooked by amateurs

The note is published in Radcom April 1982 pp320, Technical topics,
"Double stub 144MHz TVI-notchfilter" - it is also found in Technical
topics scrapbook. see

Another bleater that feels he needs five newsgroups to make a point.

We all know Morse testing is going to disappear, we all know it will take
3-10 years to do so. So your problem is whether to study or moo.

Dick N&#65533;BK with apologies for the crosspost

The W25FM was an export only version as I remember, but like as not the 'export' also included the MoD.

On a 13.8V supply they were spec'd to do 25W continuous, but 35W was more common, and I've even seen 'em do in excess of 50!.

As someone said, treat it as a W15FM, including the PA alignment - it is only a higher power version of the normal PA output stage.

Let us assume that the interference is really being caused by your very strong 50MHz signal getting into the antenna amplifier via the input connection (I'm sure that this will be the main cause, but it may not be the only problem). However, what you essentially want is lots of attenuation 50 - 52MHz, and as little as possible elsewhere. However....

Using coaxial stubs CAN be very effective, but there are several serious problems with simply adding a simple o/c quarterwave or s/c halfwave stub across the input of the wideband amplifier. These include:
1. The width of the notch will be so wide (even with the lowest-loss coax you can find) that you will also kill the TV low-band (Ch2 - 55.25MHz - will, of course be the worst affected).
2. As well as having a notch on 50MHz, here will be notches at odd multiples of 50MHz (if quarterwave) and all multiples (if halfwave). This may make a bit of a mess of several other TV channels.

The obvious solution to the width problem is to make the notch narrower. With stubs, you can do this by cascading similar stubs, each separated by a quarterwave of coax. This will also greatly increase the depth of the notch. A single stub will give you a notch of 25 to 30dB, and two stubs will increase this to nearly 60dB (I doubt if you'll need anything like this). However, this will not change the 'harmonic suck' effect (although these sucks will also be narrower).

You cannot eliminate the multiple harmonic sucks, but you can move them around so that they do not fall on those frequencies which you want to receive. You can do this (for example) by adding capacitors or inductors in the appropriate places (I won't go into this here).

You will probably be better off with a circuit using only capacitors and inductors. However, there will need to be more to it than the simple equivalent of a single coax stub. I have a typical circuit in mind, but you would have to calculate the values or do some 'jiggling' to values obtained by means of 'inspired guesswork'!

Having said all this, I'm sure that you are not the only one having trouble with 6m hitting TV (antenna amplifier or not). I wouldn't be surprised if there are several off-the-shelf filters which are purpose-made, and don't cost too much. If not, let me know - I'll move to the USA and set up in business!

73,
Ian.

Right, for further amusement go to <URL:http://www.deja.com> and search
for T10R6 (using settings of "all" and "complete"). You will then find a
previous thread abouty these things, though it won't help with your
project...

[...]

>No Xtals in it I think I got it at a rally for £10 because it had no Xtals,
>control box, mike or cable

It will work with standard W15FM control gear, should you want to go down
that route, or could be converted to "local" operation, particularly if
you only want one channel, eg for packet or whatever. Getting the full
ten channels is just a matter of fitting the full-length oscillator board
and completing the wiring, though where one gets 10-channel boards from
these days I don't know. Real pity about Garex disappearing...

>OK The transistor is a TRW PT4236c

Unfortunately can't find data on that (or any other TRW devices - did
their RF transistor business get sold to someone else?) on the web. You
probably need to track down someone with an old databook.

Before retirement, I worked for a major aerospace company and among a lot of
other things did a fair number of crystal measurements. I used an H-P 3577
network analyzer and HB fixtures along with some software that I developed.

The '3577 had the useful property of not only being stepped in frequency but in
amplitiude so that I was able to do power sweeps on crystals as well as
measuring (deriving) the motional parameters.

On one missile program we did encounter a batch of one supplier's crystals that
seemed to be "lazy." It's been a while and I don't remember exactly what power
level I started at, but it was 10 dB below the minimum output of the analyzer.
(The fixture had 10 dB loss).

The procedure was:

1) Install the crystal and at minimum power determine series resonance and ESR.

2) Step the power X dB higher and sweep the frequency and determine series
resonance . Record drive level, ESR and frequency. Repeat until a
user-specified upper power limit was reached.

3) Reverse the procedure, decreasing the power X dB per step.

4) Plot the data, ESR v. drive level.

What would be observed with a "lazy" crystal was a high value of ESR at the
beginning of the sweep with a steep, but smooth decrease as the power increased
and then a leveling off to a nearly constant (normal) lower value. When the

direction of the power sweep was reversed, the ESR would remain almost constant clear back to the starting point. In other words, there was hysterisis.

If the process was reversed, *without* removing the crystal, i.e., some excitation, albiet low level remained, the hysterisis did not recurr.

To me, the behavior in filters of crystals with this characteristic is problematic. If the signal always remains low, the crystal(s) might stay lazy, but with low signal levels, is nonlinearity an operational problem? On the other had, once the crystal has been hit with a big signal it isn't lazy anymore so do we care?

I dunno. Interesting problem.

73,

Wes Stewart N7WS

Quite a trivial method of observing sleepy crystals is to build an
oscillator with adjustable gain or negative resistance often just a
varying supply will do.
As the gain is woulnd up a good crystal will increase the level of
oscillation smoothly a sticky crystal will wait una certain vel is
reached and sprilife at full amplitude.

630. Re: Wide band 90 degrees phase shift

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-28 17:46:14 UTC
From: Gullik Webjörn <webjorn@flysta.net>
Message-ID: <3A745AE6.F1C5F845@flysta.net>
Source record: 55144

One way is to split up a single phase signal by feeding two balanced mixers where the LO is derived digitaly from a divider at exactly 90 degree.

The 2 (I/Q) signals are then heterodyned back to their original, this time using inphase LO to another pair of mixers.

Since the same frequency can be used in all LO cases, exact freq is unimportant.

Dave -

Traditionally, 6m has been the best way to get the "Worked all channel 2's" award. Various low and high pass filters, even (maybe especially) those that are effective on HF tend to be ineffective on 6m. The main problem is that 6m sits right in the middle of what would've been TV channel 1. TV sets tend to have RF front ends that are very poor in terms of strong adjacent channel signal performance. Also, TV's are usually poorly shielded (how many 15KHz harmonics can you count?) so 6m will be picked up by the power wiring and the TV circuitry itself!

What to do? I can't say what if anything will work for you, but here are a few things to try. I'm assuming that your 6m rig is clean, so my suggestions all apply to the TV system. 6m harmonics should not be much of an issue even if present because they impact only one VHF TV channel (11 I think). The basic goal here is to reduce the 6m signal strength at the TV's, TV amp and TV antenna.

1. Move your 6m dipole as far from the TV antenna as possible. The dipole is physically small (10' or so long), so this ought to be easy to do.

2. Keep the 6m and TV ant cables as far apart as possible. You say that you get an SWR of 1.3:1 WITH a tuner? Better to adjust the 6m dipole so that you have a low SWR *WITHOUT* the tuner, assuming that you're feeding the dipole with coax. If this turns out to be the problem, a "current choke" balun at the dipole may also help. If you're feeding the dipole with twinlead, you need to be more careful about what is near the twinlead's path from the antenna to your radio. In either case, the idea is to prevent the 6m antenna feedline from radiating.

3. Orient the 6m dipole so that the TV antenna is directly off the end of the dipole. Putting the TV antenna in an antenna null is the simplest way to reduce the 6m signal level at the TV antenna.

4. Choke/filter the AC power lines feeding the TV amplifier and the TVs. Radio Shack (and others) sell a ferrite core for this. I think they're fairly inexpensive - $3 for 3 or so...

5. Build quarterwave stubs tuned to 6m and install them at the antenna inputs to the TV amp and the TVs. This will selectively reduce the 6m signal level to the amp/TVs. It's possible that the only one you'll really need is on the TV amp - assuming that it's the only box being overloaded. If channel 11 is used in your area, the stub may also affect it. If so, the stub may not be a good idea. (BTW, the halfwave stub

suggested elsewhere would also affect the 2nd harmonic of 6m. Lucky for you, 100MHz is not a TV channel. Unlucky if you're using the same antenna for FM broadcast!)

Good luck. Enjoy 6m!

632. Construction elmer in Central Connecticut?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-28 17:59:10 UTC
From: dcollin@connix.com
Message-ID: <3a745b6a.12226292@news.mybizz.net>
Source record: 55125
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur,rec.radio.amateur.equipment

I'm a 46 year old extra class ham (since 1992) looking for an elmer to help get me started in building. I'm located about 5 miles from ARRL HQ.

My interest (today) lies mainly in building QRP CW tranciever kits. I realize that today's kits have excellent instructions, detailed PC boards, and are easily assembled by anyone who knows which end of the iron is hot ... but I don't ... grin!

I'd like to build a Oak Hills Research Norcal 40A for 30 meters, as well as their watt meter and digital freq display. Pretty ambitious for a guy with NO building experience (outside of dipole antennas, and connectors ... g!).

I could use a lesson or two in soldering techiniques (no surface mount stuff, yet), desoldering (now THAT might come in handy ... grin!), winding toroids, equipping a workbench (tools and instruments), and the like. Just enough to get me going, I'll take it from there. If I pick up some theory along the way, all the better, but building a kit doesn't require you know how it works (!).

I'd be more than happy to travel to your QTH if getting around is a problem. I'd pay for any phone calls. Hell, I'd even buy ya lunch! Anyone got a Saturday or Sunday (or two) free?

Thanks,

Dennis KD1JT

> Classic case of TV frontend overload. Yes, separate the antennas as
> much as possible!

Don't forget, as others have written, the TV is poorly sheilded and can pick up RF from anywhere. Get the dipole as HIGH as possible. This not only gets it away from the TV antenna, but it also gets it away from the TV, the power wiring, etc. etc. etc. If you can construct a small beam, it will be better than the dipole at not radiating downward (towards the TV).

If you don't have a balun at the dipole, definitely get one there - doesn't do a lot of good in the shack (for this problem). Also, as someone else said, get the dipole resonant, same issue.

Ferrite chokes on the power to the TV is a good plan, too.

Don't expect that the problem is that you are transmitting on the TV's frequency or IF (I assume you have checked <g>). TVs are TERRIBLE at any sort of strong signal, even if it isn't close to the TV's frequency. Under Part 15, it's the TV manufacturer's responsibility to deal with it, but in practice, that doesn't do any good. The only thing to do is be sure the TV doesn't see a strong signal, and the easiest way to do that is to radiate your RF away from the TV and it's antenna.

> Scott
> N0EDV
> No TVI with DirecTV :)

I manage to get into my TVs with a ground mounted vertical, even with cable. You probably have an antenna in the sky away from the TV. My antennas in the sky are no problem. Chokes help some, but that plastic case on the TV lets the RF right on in.

I might suggest you take the amplifier in the TV out of service. They will generally respond to a 50-MHz signal as channel 2 is JUST above our 6-meter band. Chances are you are saturating the amplifier. It's worth a try.

Hi all and thanks for reading my post

I have been out of AR for 14 months (due to an accident not loss of interest) and am now looking to get back into it.

I am looking at building a lot of my own gear this time around and one project is an antenna rotator. Although I have searched high and low on the internet, I can not find anyone that has built a rotator system from scratch. I have found a direction indicator but that's all.

Has anyone built or know of an article that describes building an antenna rotator? If so could you please point me in the right direction or send me a scanned article, but please email me direct after you have removed the SPAMJAM.

It's just as simple to vary number of turns, as you would do in practice,
until the desired inductance is obtained.

Download (in a few seconds) program TOROID from website below. Enter core
dimensions, core permeability, number of turns. Program will tell you wire
diameter and inductance. Also capacitance to tune to a specified frequency.

Phil,

Looks pretty good to me. Always did like phasing SSB generation
better than the filter method (guess I'm just old-fashioned). I don't
see the 3.7 MHz upper limit as a problem: just thinking about the
circuit, I see me using the 10 MHz oven timebase that is going to be
the clock for the synthesizer (and for the receiver) as the source for
the modulator and mixng the output of the modulator up to the
appropriate band. That way everything is locked to one master
oscillator.

I'll going to file this with the other info I'm gathering to
construct myself a new transmitter now that I've decided to get back
into ham radio after a 20 year absence.

Yes
I had a friend in the Ukraine who used a geared motor attached to the back
axle of a Lada to turn his beam.
It could have turned the whole block of flats.

I used to use a heavy duty stepper motor to turn a VHF beam in my attic
(weight taken off motor by suspending antenna from a string, but I have not
seen any stepper motors that would be up to the job for a long time.

Hi out there

Finished the 40-40 qrp rig and have a question on the key line.
On the pcb there are two points for the key, the Tx key and the
Rx key.
The first goes through 2 registors (10k & 22k) to Q3/2N3906,
the second one to pin 8 U4/NE5532 throug the D4/1N4148
and 1M registor.
My question is which is to be used for the +key line? or both of
them?

Thanks for any idea

Bill: Doug DeMaw had a very nice, very simple DSB circuit that I've been planning on building. It appears in several of his books and in the Feb1997 issue of CQ. It essentially gnereates a DSB signal by the TX equivalent of direct conversion. His cirucuit has op amp mic amplifier to a two diode balanced modulatior. The balanced modulator is also fed by the local oscillator at the operating frequency. Output of the blanced modulator goes to the RF amp. Very simple.

I'm planning on building one of these for 17 meters. LO will be a VXO. You could easily throw in a direct conversion RX and make it a very simple QRP transceiver.

This sequence circuit is otherwise known as the polyphase circuit.
I have used it on recieve as well as transmit for SSB. It gives very
accurate phase shift and is tolerant of component variation. However
it needs lots of passive components and is quite lossy in band. Out of
band signals are less attenuated which may cause a problem with
dynamic range on receive.

Richard

In addition to Bill's advice, you might also want to ask in some of
the ham radio newsgroups. Perhaps someone in there has experience
with this radio and can offer advice. In fact, I've crossposted this
message (from rec.radio.shortwave) to a couple of those newsgroups for you.

Hi Chuck!

Re. coil Q: I understand the idea of using a thin wall PVC core for coil winding.
Along the same lines, what about using the following alternatives?

- bare copper instead of PVC coated

- other kinds of core material, such as ceramic or glass?
(wasn't ceramic very popular once upon a time?)

- rather large gauge wire instead of the tiny #22 used in several designs
(wouldn't a lower resistance to reactance ratio also help raise Q?
Moreover, a large coil can be made air-wound)

Best regards,

Filippo N1JPR/I2

In one word; NO.

The 8044 is a ASIC made to Curtis sole-owned spec's.

The 8088 is a CPU which gained fame and is also known as the XT computer 'brain'.

These devices are also of unlike packaging.

Bests,

Hi Ken,

There are several methods for using coax in a antenna trap. One
of them uses the coax for the inductor and the capacitor. Another
uses a standard inductor and length of straight coax for the
capacitor. I'm not sure which one you are looking for.

I use a coaxial trap dipole that is set up as an inverted V.
Mine is for 40, 20, 15, and 10 Meters but making one for 30/17/12
should be a simple matter. On my antenna the coax is used for
the inductor and the capacitor.

I used HamCalc, written by George Murphy VE3ERP, to design the
traps. One of the places you can get a copy is from
"http://uhavax.hartford.edu/eetsw".

For my traps forms I used PVC couplings, in various sizes, and a good
quality Belden RG-59. This so that some of the characteristics will
be stable, like the capacitance per foot. You won't need that much
so the cost shouldn't be an issue.

For tuningyou will need a "grid dip" meter. The "grid dip" meter is
used to adjust the traps, before they are connected to the antenna.
Once the traps are on the antenna, you will not be able to check
the trap frequency without disconnecting them.

Once the traps are tuned, build the antenna and adjust the
wires for the various bands starting with the highest frequency
band. In your case that would be 12 meters. Then work you way to
the lowest band. The length of the highest frequency section will
be in the normal range but on the lower frequencies, the traps
will act as loading coils and shorten the over length.

The antenna completed should be tuned in it's operating position.
This may mean that you will have to raise and lower it about a
dozen times to get all the lengths right. I used a mast with a
pulley at the top so it wasn't much of a problem. If you can
borrow an "antenna analyzer" it will greatly simplify the tune
up procedure. With an analyzer you can quickly see how one
adjustment affect you current band and any of the other bands.

I get a SWR of less than 1.5:1 on 40, 20, 15, and 10 Meters with very good bandwidth. On 40, 20, and 15 it covers the whole band but on 10 Meters it's only good for about 400 KHz. The match is close enough to 50 ohms such that I don't use a tuner. I use a 1:1 balun to feed the center of the dipole, but it's not absolutly necessary. You can probably get away with just using a coax choke.

A very good description on the construction of a trap dipole can be had at "http://www.nerc.com/~jdegood/coaxtrap/".

Good Luck
Martin K7MEM

666. Wiring up equalizer to microphone.

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-29 19:19:36 UTC
From: Scott McClements <yetbbwa@grove.iup.edu>
Message-ID: <3A75C248.212BE649@grove.iup.edu>
Source record: 55055
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc

Hi all,

I have been playing around with different microphones and I am getting tired of
it. I bought some D-104s and put a Panasonic electret condenser full range
element (1K Ohm) in the D-104 head in place of the crystal element (no pre-amp).
The only problem now is, its way too muddy (bassy) for SSB use. I didn't want the
hassles of playing around with capacitors trying to fix up the audio.

Then I found this 8 band equalizer made by W2HIY. I don't like the Radio Shack DJ mixing board look of the unit, nor the layout, nor the price.

Then I started looking around and found a 31 band graphic equalizer can be had new for
around $120 (http://www.artroch.com/351/351desc.htm) and used for under 100$. I couldn't think of any reason I couldn't wire up my microphone to this thing. I was thinking of building
a box with the standard 8 pin connector on the front and running a 1/4" unbalanced
line into the EQ, then back into the adapter box and out the front to the radio. Now, I am
a novice when it comes to circuit design..but this seems pretty simple. The only
thing I figured I have to worry about is RF getting into the big mess. If I wrap
the power line to the EQ over ferrite and do the same in my box on all the lines,
and use a few capacitors here and there in my adapter box, should I be ok? Or will
this type of EQ just get destroyed by the smallest amount of RF and be a headache
to cure?

This exact kind of control over my microphones response is what I desire, but
is this a feasible project?

Thanks,

Scott McClements.

668. Re: Raising coil Q in regen RX

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-29 20:01:22 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <954i50$la2$1@uranium.btinternet.com>
Source record: 55064

To maximise Q of solenoid coils -

Don't use pvc insulated wire. For close-wound coils use enamel insulated magnet wire.

Wind on a ribbed former. The insulation is then nearly all air.

Don't use a close wound winding. Space adjacent turns such that distance between wire centres is 1.5 times wire diameter.

Coil former diameter to length ratio: Don't have long slender coils. Don't have short coils with thin wire. It's not critical but length = diameter is OK.

If you double all coil former dimensions and reduce number of turns to give same inductance then Q approximately doubles. Big coils have big Q !

But if you intend to make a super-selective tuning coil by using reaction around an amplfier just short of oscillation point - why bother ? Any old coil will do for that. Such coils may be small but should have physically very stable dimensions.

Hey yall.
I was curious if anyone knew anything about bottling brew in glass bottles which have twist off caps. I have a bunch of Shiner Bock bottles which use the twist off caps, and i have a circular key chain that i can use to reseal caps on airtight (i tried with vinegar and baking soda). If i clean these out thoroughly and sanitize them, would they be ok to bottle in?

If anyone has experience or insight, i would really really appreciate it.

Don't re-use the caps. Buy some caps made for twist-off bottles. In
Canada, they are usually silver as compared to the gold for a regular
bottle.

I'm looking to start building QRP transciever kits. I need to equip a bench for such work. There are only a few "big ticket" items I can see buying, and the choice might be important. Does anyone have any recommendations for:

A multimeter? Digital or analog? Features? Price?

A soldering station? Weller? WLC100 (40 watt adjustable) OK? Don't bother, just get a simple iron?

A vice to hold PC boards? Panavise? Model?

Of course, I'm open to cost-saving alternatives that some of you have found to work (hams tend to be a "thrifty" lot).

Thanks.

676. Re: Wide band 90 degrees phase shift

This is the third method of SSB and has been around since Weaver
proposed it in the dark and distant past.

I don't think you noticed that he said both are same physical size and pinout, that rules out his 8088 being a CPU. I assume both are Curtis chips, but not sure about 8088.

Latho,

I recommend desoldering the "caps" to take them "off", that way you won't
ruin the leads and could probably sell them at the local Hamfest ;)

Scott McClements.

P.S. rec.radio.amateur.homebrew is for the amateur who builds his/her own
electronic equipment, primarily related to Amateur Radio.

I have found that a good soldering station is the Weller WSD80. I usually use the LTA 1.6mm tip, although I have a selection of all tips. The initial price is high however, so for beginning work, a simple iron may be better...just a thought.

Good day!

Lacking that I wonder how a square-cross-section coil wound on two insulators, e.g. plastic strips, in the form of an X would do? I'm guessing quite well...

I don't think this is correct. While everything is the same right at the resonant frequency, I'd expect the off-frequency performance of a low-Q coil to be worse (wider bandwidth) than a high-Q coil. If you're right at the zero-resistance point at the resonant frequency (thanks to feedback) you're still in the positive resistance region off of resonance, so Q should matter (IMHO -- I haven't tried to do the math).

A replacement mic element can probably be purchased for a tenth of
that, and it is primarily the mic element that effects the audio
sound. Buy yourself a pile of mic elements (tuned for various vocal
ranges), try them all out, use the one you like, and return the others.

If you want different sound for different modes, say for FM and SSB,
try an arrangement similar to the Heil HM-10 microphone, with two
elements controlled by a simple two way toggle switch (or three
elements with a three way switch, or four elements...).

In the end, this will bs far cheaper, and a lot less mess to worry about.

No but close.

But I guess if I used an electric motor to drive the differential it could be feasible.... but wouldn't the twisting moment on the shaft going up the tower be horendous (about 11m)?

From: Filippone <filippone@my-deja.com>
Message-ID: <956c8rsdv1@nnrp1.deja.com>
Source record: 55083

To sum up:

- large rather than small conductor

- uncoated, or enamel insulated at most

- approximately 1:1 length to diameter ratio

- ribbed former, or better no former at all
(easier with thick wire)

- another option: two or more side spacers instead of a full former
(this is quite common in big coils in old transmitting equipment)

- also, thin wall low dielectric former (I am tempted to use a large
lab glass vial or a section of thin walled glass pipe).

Thank you Reg & Mike!

If all the radio's selectivity comes from one LC circuit, I think all
is worth trying!

Have you ever heard of a special glue for use on coils? Does Araldite
ring a bell? I last heard about it perhaps 20 years ago.

>> The early 1980's Crays were also fluid cooled

True. Not water cooled. They used a fluoride based compound, somehow related to teflon and old breast implant gel. Highly inert, nonconductive, crystal clear, expensive. I think it was supplied by Montedison, a since dismembered Italian chemicals company.

I think the Sony PS2 uses a sort of silicon fluid bag for chip cooling. If things go on developing the AMD / Intel way (as oppoased to the Transmeta way) we may see a resurgence in liquid cooling.

Using mineral oil or fluoride has its pluses. No worry about boiling and shorting. In the case of oil you need oil resistant gaskets and seals, though.

Although many of us consume brew while pursuing our hobby, only a few
actually make their own suds.

I was afraid the only responses I would get would be get a Heil, try this element try that element. First off, you couldn't pry the D-104 out of my cold dead hands. I like it, it just feels right. Add a good electret condenser element with a wide flat response and ~10 bands of EQ and you accomplish whatever *exact* sound you want. Scoop the mids, boost the treb. you can perfect the sound in a few minutes, why would I want to play around with swapping elements when you mount them in their final location and find it sounds different than it did when you tried it out in the open?

Not to mention you got a mic that sounds as good as a studio mic and looks like it belongs in the shack and not a commercial radio station.

Scott,

I'm really not trying to bad mouth in any way, but this is how I see it.

Your project is definitly feasable, but I can't see what kind of return your getting. No one on the other end is ever going to hear the high end of your audio. Your rig is going to filter most of it out, and a tight audio filter on the receive end will wipe out all but about 2.1 KHz.

About the only enhancement that will go over the air is the increased low end, which you want to eliminate anyway.

You have taken the original element out of the D-104, which was already designed and optimized for SSB service, and put in a full range element. Now you have broadcast quality audio coming out of the microphone. Then you are going to put a equalizer between the mike and the radio and adjust it back to the same thing it was before. And in the process, spend a little money.

No one really cares about how smooth your voice is. All anyone wants is to be able to hear and understand you.

I have read:

OPTIMIZING SSB TRANSMIT AUDIO AND REVIEW OF THE W2IHY 8 BAND AUDIO EQUALIZER AND NOISE GATE

http://www.eham.net/articles/1582

It's kind of interesting but very self serving. The guy, W2HIY, is just trying to sell his product. Some people can make a very convincing agrument for just about anything.

Maybe all you need is a speech processor. A lot of new expensive rigs have these processors already built in, but the older rigs don't. If yours doesn't that you might want to try your hand at building one. A fairly simple design is below. All the parts should be available at Radio Shack.

Build An Audio Speech Processor

http://www.rason.org/Projects/speech/speech.htm

If nothing else, it's cheap to build, and if it doesn't do what you want, you can throw it away without worring to much. You may want to do a web search on "ssb audio processor". There is a lot of info on this kind of thing.

Well, I don't know if I have been of any help but good luck anyway.

> recommendations for:
>

How many QRP transciever kits are you going to build? You only need
one or two. I have 3 and I think that's excessive. :)

Just an initial word of caution. Don't buy any big buck
test equipment unless you already know how to use it and what
features are useful. You will get lots of advice on features
that people think are important, but you won't know for sure
until you try them. Get together with some friends or club
members who have different pieces of test equipment and
know how to use them. Learn from them first and then invest
your money.

A lot of test equipment is very specialized and you may be
better off borrowing. For example, a "grid dip meter" is a
real handy thing to have, but it's not something that your
going to use all the time. Your money might be better spent
on a good antenna analyzer. Granted, you don't need to
measure your antennas all the time, but, once you get to
know this piece of equipment you will find out it can be
used for many many things, including serve as a "grid
dip meter".

> A multimeter? Digital or analog? Features? Price?

People put down Radio Shack a lot and some of it is deserved, but
Radio Shack is a good place for this one. Their top of the line
digital multimeter will only cost you about $60 or $70. Just make
sure you know how to use a multimeter or you will be blowing
fuses all the time. If you are really a "Rank begginer", you
may want to buy one of their cheaper models to learn on. Then
it won't be so bad if you burn it up.

Usually, the more you pay, the more features you get. Whether
these features are useful, or not, depends totally on you and
your ability to use them.

Digital or Analog is almost a religious issue. Some people swear
by analog meters and other like digital. Personally, I was

brought up on analog meters and prefer them, however, I also
have digital meter and they do serve a useful function.

I have a new RS Digital multimeter, an old (20 Years)
RS Analog multimeter and a old (also 20 Years) Triplett
Analog multimeter. I like them all but my favorite is the
Triplett.

> A soldering station? Weller? WLC100 (40 watt adjustable) OK?
> Don't bother, just get a simple iron?

IMHO get a Weller. I am not up on what they have to offer but
I can tell you that my Weller is over 30 years old and still
going strong. And, I can still get parts for it. You may pay
a little more up front, but it's worth it.

Skip the one at Radio Shack. A friend of mine has one. It works
kind of ok, but not as good as the Weller. The Weller will last
a life time.

Don't forget good quality de-soldering tools. Some solder wick
or a good solder sucker is in order. This will help prevent
hacking up your project when you accidentially put a part in
the wrong place.

> A vice to hold PC boards? Panavise? Model?

For all of my work, I use a drill press vice. These are small
vices that allow for angle settings. They are a little heavy,
but that helps it stay in one place when you are working on a
board. I also use lots of light and keep a good magnifying glass
close by. Maybe I'm just getting older but it seems to me that
the print on some of these parts is getting smaller and smaller.

> Of course, I'm open to cost-saving alternatives that some of you have
> found to work (hams tend to be a "thrifty" lot).

I would have said "cheap" but "thrifty" is a much nicer word. ;)

But really, one of the best cost saving alternatives is to go
to a couple of ham fests. Stay away from the big boatanchor
test equipment. There is plenty of good stuff that people just
don't need any more. Many "thrifty" hams buy and sell there.
I know I do.

Also, you could build some of your test equipment. For your
QRP rig it might be handy to have a RF Probe handy during
tune-up. An RF Probe is simple to build and can plug into
that shiney new multimeter that you bought at RS. There, now
you have made that multimeter even more "multi".

Well, enough for now. I hope this gives you a start.

Filippone <filippone@my-deja.com> wrote:

Hi Filippone. Your list is good, but, you are forgetting some things
about regens that one must remember to get the most of them.i

> To sum up:

> - large rather than small conductor

Yes, but you don't need to get too carried away. No. 10 is fine.

> - uncoated, or enamel insulated at most

Enamel is good, or teflon coated is good.

> - approximately 1:1 length to diameter ratio

I use about a 1.5:1 ratio, and find that works very well.

> - ribbed former, or better no former at all
> (easier with thick wire)

Use a ribbed former with good insulating properties. Glass would
be good, or isolantite. I find that at usual regen frequencies,
acrylic works good, too.

> - another option: two or more side spacers instead of a full former
> (this is quite common in big coils in old transmitting equipment)

This was typical of better quality regens in the so called ``low-loss''
era of the early to mid 1920's. It still works fine today.

> - also, thin wall low dielectric former (I am tempted to use a large
> lab glass vial or a section of thin walled glass pipe).

Glass will do fine.

But, you need to remember the two most important points about regenerative
detector sets....

1. Uncouple, uncouple, uncouple, uncouple, uncouple.

2. Use the highest impedance grid circuit coupling network that you
can, commensurate with a reasonable recovery time constant.

Uncouple is a key word. 99.99% of regens I have ever run across were
way overcoupled. I use typically a 1pf or less coupling, if capacitive,
or a very wide spaced 1 turn link, if inductive. It is not unknown for
OT regen builders to use as much as 6 inches of coupling (i.e., the
distance between the primary and secondary circuits).

The grid leak/grid capacitor is critical. I always use more than 10 meg ohms grid leak and less than 20pf (ideally around 5-10pf at the usual low HF ranges) of grid coupling. More than that and you are overcoupled. Use the highest leak possible but keep in mind the time recovery constant of the LC circuit in the grid leak/grid capacitor, which can be as long as 10 seconds. You make a tradeoff here. Values around 10meg-25meg are good in my hands, with input capacitors of 5pf ideal, in my hands. The usual 1 meg ohm grid leak and 100pf coupling cap is way, way, way, too much of a load on the grid circuit, broadening out the selectivity. On the other hand, 1000 meg ohms (or stray leakage) and a 20pf grid cap takes forever to recover on a strong CW signal.

IF you set it up correctly, you can easily cut the sideband off a sideband signal with a premier quality regen detector.

If you are putting your own set together, you might try some of the above ideas. I swear by them.

Good Luck

ZUT OM DE NA4G/Bob UP

(I have been running regens as my main mf/hf equipment on cw for 30 years. Properly run, they compete very well with more ``modern'' gear on the bands up to 30m or so. Improperly run, they are a nightmare. QSK is a little hairy with them, but doable.)

> If all the radio's selectivity comes from one LC circuit, I think all
> is worth trying!

True!

> Have you ever heard of a special glue for use on coils? Does Araldite
> ring a bell? I last heard about it perhaps 20 years ago.

That would be the early electron microscopy era, where it was used as an embedding medium for thin sections? Is it still available?

A glass tube with glass standoff rods should do well.

I would expect teflon would do well, too, but cost an arm and a leg to machine.

In the 20's it was not uncommon to use glass rods as the coil supports.

.....

: http://members.home.net/rbethman/813s.html
: You'll find the info at the above site. While it is not a
: single band amplifier, it shouldn't be too difficult to place it
: on 160 mtrs.
: Enjoy!
: N0DGN

I've looked at the diagram for the above amplifier project and have some thoughts to add.

*****

First: The input tune circuit is almost a must-do. Unless your using a tranceiver with a tube PA, this circuit will be hard to match to many solid state exciters (without their respective built in auto antenna tunner).

Second: The bias supply shows an extra transformer "T2" that one would not really need if the main supply was properly thought out. You would really have to know what your doing in this area if the amplifier is operated grounded grid AB2 as shown.

One method of standby mode cathode current cutoff is to keep the bias constant (at normal value 100% of the time) and interupt the center tap path of the filament transformer in the proper location. A high value series shorted resistor is simply used to develope a cutoff voltage when the unit is in stand by.

Third: Metering the Grid and Plate current is almost another must-do item. Be careful of the position of the grid current metering to ensure your only measuring the grid and not the combination grid/cathode current values.

Fourth: Get rid of RFC5 and replace it with a resistor of proper value. Chokes in the output tank to ground are old news.

Fifth: Make sure to blow a lot of air past the tube base pins and past the glass anode connections. I run almost 4KV on my quad 813 amplifier and it really heats the room up fast.

Dear Filipone,

Yes, you got the right ideas about high Q. Really fairly obvious when you come to think about it.

Araldite is an excellent multi-purpose compound --- except that its electrical properties are not defined. Electrically it is very likely terrible stuff. If it is used to construct RF coil formers use as little as possible. Better not to use it at all.

For high Q coil construction use polystyrene tubes, rods or sheets. For glue use polystyrene "dope". It can be purchased in tubes. Or it can be "home brewed" by disolving polystyrene in benzine or or in some other solvent which will completely evaporate as the 'goo' dries out.

But, I repeat, if you intend to use a coil in a "Q multiplier" circuit, coil loss does not matter because your +ve feedback, or reaction, will entirely compensate for it. Wind any sort of small junk coil and, to fix its mechanical stability, dunk it in a thin solution of shellac disolved in methylated spirits, or polystyrene disolved in benzine, or your XYL's nail varnish.

Or just wind the damn thing and see what happens. You will probably not be disappointed.

I'll let you into a little secret :- I wind my coils on dry toilet-roll tubes, or on empty 35mm film cartons, or on any smaller-diameter plastic tubing. Then I daub some polystyrene dope on the ends to make the winding mechanically secure. It never fails.

I wasn't suggesting that you get rid of your D-104. I was suggesting that you just switch out the element for something more to your liking. However, since you seemed to rule that out also, there is little else I can offer.

Of course, there have been many microphones over the years with tone controls (from a simple knob to equalizer-like sliders), including several now popular with the CB crowd, but I have always felt these were little more than a gimmic (once the sound is adjusted to the preferred point, why continue to have the controls in the way).

However, its your radio, so by all means go for it.

What exactly is your "good RF ground"??? At 6M, the length of wire from
the rig to the ground system may be a significant portion of a
wavelength at 6M. Since the TV is going blank, it sounds like
overload...if it were just interfering you'd probably get squiggles or
bars or something. Can you run the TV system without the amplifier(s)
in line as a test?

Although in a great many applications, the former material isn't all
that important (...yeah, Reg, I use cardboard tubes and PVC pipe
sections too!...), be careful about glass. There are LOTS of
different kinds of glass. Some glasses are fairly high loss. To make
matters worse, if you use glass as an insulator in a high power system
and it starts to heat, its dissipation factor typically increases rather
rapidly, possibly leading to thermal runaway. We had a serious
materials selection problem in one of our products because of exactly
this phenomenon. If you stay with fused quartz, you should be fine!

Hi Filippone,
I have some Araldite that I purchased about 15 yrs ago. This stuff is great epoxy! It stiffens in about 5 minutes and usable shortly after that. I don't know if it's available anymore. I think it is made by Ciba- Wait, I'll be back,

I'm back, I went searching , found a site
http://www.vantico-aandt.com/newco/addexn.html
It has Araldite, apparently there are several types click on the DIY link.
I have never tried it on a coil.

Skipp - I appreciate your thoughts. Past experience with 813s has shown that they really do NOT need air blown over their pins. In fact simple non mechanical convective cooling does well. This design has been a lot more thought out than you may believe. B&W even duplicated it and sold it as a commercially available amplifier.

The timeframe when this design appeared almost every transmitter or transceiver was tube finals. The copyright of the Sixteenth Edition was 1962.

T2 if you look carefully, is apparently an isolation transformer as the primary and secondary are 110V.
Once again - look carefully as that section is controlled by the VOX relay.

The grid and plate metering ARE there. The meter is singular, but multipurpose through switch position. I believe the components provide the necessary isolation.

RFC5 is a rather standard amplifier design. It is a protection choke, typically 25 mH in the event that there is a breakdown that allows full DC Plate to appear on the output. It becomes essentially a short and takes down the power supply. This keeps folks near the antenna from getting the "advantage" of playing light bulb unknowingly. This technique is used in almost every amplifier design I have ever seen.

From: gapershi@aol.common
Message-ID: <20010130200430.04734.00001577@ng-mp1.aol.com>
Source record: 55007

This may be of interest to anyone who homebrews MF and HF receivers.
For the past 3 or 4 years I have been working on my own design for a
general coverage receiver. Recently I have made some improvments to
my front end design. I have carefully documented the whole radio and
placed it on a web site. I was able to extend the dynamic range an extra 20dB
from what I had previously achieved. Also some minor tweaks have been
added recently.

I should mention that I am not a ham radio operator, but enjoy shortwave and
medium wave dxing. I have a background in electronics, (25 yrs) but I am
not an engineer.

My radio can be seen at this address:

http://members.aol.com/gapershi/radio.htm

If anyone knows of any homebrew HF radios with good documentation,
I would be interested in seeing them.

Thanks,
Gary Pershin

I don't think the differential bought much gear reduction.
I wonder if an old automobile gearbox would give appropriate reduction with one of the gears? Hmmm... must be a better way.

Without better specification requirements, it is hard to give a good answer...however, based on your 12v power supply requirements and your TO-220 case preference, I would recommend the OPA544T. This is rated for 5 amps, and from 10-35 volts...maybe a bit excessive, but usually runs about 12 1/2 dollars a shot...cheaper then other high-power opamps I've seen.

Good day!

RST Engineering (www.rstengineering.com) is pleased to announce the upload of several engineering spreadsheets for your dining and dancing pleasure. Please use them with our compliments.

WIRE TABLE -- The standard AWG wire table with a calculator for resistance, voltage drop, and temperature rise for any wire gauge from 0000 to 40.

RF WAVES -- Free space path loss, receiver margin, and dbm/microvolt conversion.

SINE OSCILLATOR -- making a fairly low-distortion sine wave oscillator from a couple of opamps and a handful of passive parts.

COMPLEX IMPEDANCE -- Transforming series and parallel r+jx back and forth at various frequencies; adding, subtracting, multiplying, and dividing complex numbers.

MAKING L & C -- making your own inductors and capacitors.

MACHINE SCREW TABLE -- A simple table for screws from 0 to 1/4", sizes, taps, drills, dimensions, washers, and nuts.

STANDARD ATMOSPHERE -- The United States Standard Atmosphere with density, mach, temperature, and pressure. A calculator for pressure at any given altitude.

Please enjoy them with our compliments. If you find any errors (out to the first decimal place) please advise.

Excuse me. Too much pain medication last night. RFC5 is a 1 mH, but for the same reason. You do not want full plate voltage on the feedline and antenna if the blocking capacitor(s) fail. Usually it is a 2.5 mH.

Excellent advice, Bob!

> Enamel is good, or teflon coated is good.

With large wire spacings and large coil diameter, the
dielectric is not too important. I would prefer enamel wire
from a motor shop to vinyl covered house wire, however,
because of the much higher loss of plasticized PVC.

>> - ribbed former, or better no former at all
>> (easier with thick wire)
>
> Use a ribbed former with good insulating properties. Glass
> would be good, or isolantite. I find that at usual regen
> frequencies, acrylic works good, too.

Actually acrylic will have lower dielectric losses than
glass and many ceramics.

>> - another option: two or more side spacers instead of a
>> full former (this is quite common in big coils in old
>> transmitting equipment)
>
> This was typical of better quality regens in the so called

These are easy to make with Plexiglas or Lucite too. Just
file notches to hold the wire.

>> Have you ever heard of a special glue for use on coils?
>> Does Araldite ring a bell? I last heard about it perhaps
> 20 years ago.
>
> That would be the early electron microscopy era, where it
> was used as an embedding medium for thin sections? Is it
> still available?

Araldite is a trade name for many related adhesives and
resins. Today most are generically known as epoxy. Their
dielectric loss properties are not as good as the the old
standby, polystyrene Q-dope.

> I would expect teflon would do well, too, but cost an arm
> and a leg to machine.

Teflon is easy to machine unless you need precision tolerances. Then you need to cool it in liquid nitrogen first. :-) It is somewhat expensive. Acrylic tubing is availabe from most plastics distributors. A section cut from a plastic soft drink bottle (polyethylene terephthalate) makes a reasonably low loss dielectric but it may be too flimsy.

Q-dope is still sold, but you can easily make your own. Get a pint glass bottle and fill it about 3/4 full of toluene (which can still be bought at Home Depot around here). Add polystyrene peanuts. You would be amazed at how many will go in the bottle. Soon you will have a rather sticky mess that looks much like a liquid with fur-balls in it. Cap the bottle tightly and let it sit for a few weeks. Think of the polymer chains as blobs of tangled spaghetti. In the solvent, they will eventually untangle and uncoil. This takes a while so don't think they did not dissolve if the solution looks cloudy the next day.

Eventually almost all of the polystyrene peanuts will dissolve. You may have some sediment (often pigments and contaminants) at the bottom of the bottle. Add some additional toluene if the solution is too viscous (thick to non-chemists).

When using toluene or any other flammable solvent, stay well away from flames or sparks. Avoid breathing the fumes and work in a well ventilated area. Acetone is usually an acceptable substitute for the toluene and it is far less toxic. I have made quite acceptable coil dope either way.

[Some trivia... Originally coil dope took its name from solutions of cellulose esters, which the original coil dopes were made from. In the early days, these were cellulose nitrate and later came cellulose acetate, propionate, or butyrate. In manufacturing these esters, the solutions are still known as dopes. Likewise in cloth wing aricraft, the fabric coatings are called dopes. I have no idea of the origin of the term, however. Of course, sniffing too much of the solvents will turn you into one! (And destroy your liver too!)]

>It has Araldite, apparently there are several types click on the DIY link.
>I have never tried it on a coil.

Araldite was one of the very first epoxy adhesives, but today it's
nothing special.

Used on a coil, it will have just the properties you'd expect from
epoxy:

* reasonably low loss (but not as good as say polystyrene)
* significant temperature coefficient if used for a VFO coil
* strong, but also possibly too strong to allow adjustment by peeling
off turns of thin wire
* good high-temperature performance on a PA or ATU coil (better than
soft thermoplastics, but not as good as ceramic or PTFE)
* very poor lifetime in sunlight.

Murray I have been thinking about what you said regarding the
differential and also note what you said below

Perhaps the gearbox and shaft drive off a motorcycle would be the order
of the day.... I haven't investigated this but I see no reason why it
couldnt work after all if those gearboxes can handle 75+hp they should
handle an antenna, their compact size has to be a plus too.

720. Re: PLL for Broadcast Radio (87.5-108MHz)?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-31 10:10:39 UTC
From: TC <cadigant2@uofs.edu>
Message-ID: <3A77E49F.B7490C56@uofs.edu>
Source record: 55022

Tobi,

Several years ago I built a PLL kit from Panaxis to send the audio from my scanner out into the back yard. Works great. I have it set up for mono, but I believe you can also set it up for stereo FM.

I have 2 other (unbuilt) kits for FM. They are from DC Electronics. They are based on the Motorola PLL chip MC145170-1 and controlled by a preprogrammed microcontroller chip PIC 16C54. I got these are so I can eventually learn some more about PLL circuits and build something for 6m. They are priced right. I don't have their e-mail address on hand, but I am sure you can hunt them down on the web.

There is a review of several FM broadcast kits at,
http://www.geocities.com/Area51/Nebula/3736/

hope this helps,
73,
Tim C (wc1f)

721. New UK Amateur Radio QRP Event for 2001

Newsgroup: rec.radio.amateur.homebrew

South Normanton & District Amateur Radio Club,
in Association with the G-QRP Club, will be holding
"Junction 28 QRP Convention" on Saturday 17th March 2001
at the Village Hall Community Centre, Market Street,
South Normanton, near Alfreton in Derbyshire.
Just 5 minutes from Junction 28 of the M1 motorway and the A38.
This will be a traditional radio event, organised in the true spirit of
amateur radio.
All under cover, there will be lots of traders with components, kits,
vintage and radio surplus, plus special interest groups and club stands.
Lectures throughout the day from Rev.George Dobbs G3RJV,
Rob Mannion G3XFD (PW editor), Tex Swann G1TEX (also from PW)
and Douglas Pitt of the N.B.T.V.A. (Not to be missed!)
Hot and cold food and drinks will be available, plus a licensed bar.
Talk-in will be provided by special event station GB0LOW on S22.
Doors open 10.00am. Admission is just ?1.00. Free prize draw.
Further details from the organiser on 01623 465443.
We look forward to seeing you there!

I did this with an old windscreen wiper motor.

I had a bearing in the roof pitch and dropped
the aerial pole into the roof so I could run
things in the dry.

The motor already has a big step down so it
drove a little pulley with a big pulley on
the bottom of the pole made out of three bits
of chipboard bolted together.

It was gloriously Heath Robinson but worked
a dream for five years till I moved.

I had a 360 degree pot (I've not seen them
recently) driving a panel meter calibrated
in NSEW.

The third method as I understand it uses an audio subcarrier at around 1750 Hz for a 300=-3000Hz bandwidth. On receive the RF is direct coverted to audio in the first pair of mixers. The first LO is at a frequency in the middle of the SSB passband (ie carrier+/_ 1750Hz). The I/Q signals are filtered by a sharp LPF at 1800Hz. This has the effect of "folding" the audio around the 1750Hz subcarrier. The audio is then demodulated by a second pair of mixers driven by a LO at 1750Hz in quadrature. The advantage is that you dont need a phase shift network at audio but the Low pass filter must be quite sharp

==========
Indeed ,although it is a hobby ,things can be overdone .

For a crisp radio communication microphone passing up to 3000 Hz just use a
$1 electret mic capsule.
and a home brew amp which fits in a desk stand (if that's what you prefer)
A simple but effective design /construction project including Hi- and Low
freq boost adjustments can be found in QST - August 1989 , pages 18 - 19 -
20 - 21
The amplifier involves a 2N3904 transistor and a 741 OpAmp .
The circuit needs minimal 9 volts DC supply ,either from a PP battery or
from the transceiver.

Suggest you keep it simple

73 Frank gm0csz.kn6wh@ukrs.org

PS : The electret mic capsule can usually be found in scrap telephones. I
have a number salvaged from phones . Tandy sell a capsule as Electret
Condenser Mike Element Cat. No. 270 -0923

Suggest to keep it simple

Hi there...
I want to bulid a FM-Test-Broadcast-Transmitter
is stereo for testing selfmade receivers. The
only problem I've got is that a free running VFO
isn't as stable as I wish. So what I need would
be a PLL for 87.5 to 108MHz in 50kHz steps.
100kHz would also do but not as good as 50. The
circuit shouldn't heve IC's that I've got to
chase to the end of the world. I want to get them
very quickly with not long searching for any
things...

Thanks a lot for you help

Well, two suggestions, neither of which is exactly what you asked for:

First, I like WinSmith quite a lot. There are things that could be better about it, but it lets you build a ladder network of R, L, C, lines and transformers, and adjust them easily to quickly visualize transformations on a Smith chart plot, simultaneously at a set of frequencies. But...it costs around $80 as I recall.

Second, there are do-it-yourself solutions. You could program Excel to plot reflection coefficient, and even arrange it to handle some simple ladder network things. Plotting the typical Smith chart lines might be a challenge! You could make quite a decent Smith chart program in SciLab, which is freeware. There are tools to do a user interface something like WinSmith. But it would be a fairly serious programming effort. It would be a very nice contribuiton to the ham/RF community if someone undertook this, though, and made it available.

I know there are a few freeware Smith chart programs out there, and I'm sure someone will post pointers to them, but none I've seen makes me even remotely interested in switching from WinSmith.

Cheers,
Tom

Thanks for the input. I looked at WinSmith. I would buy it, but I can't find anywhere that will allow immediate download after purchase since I need it asap. I've spent two days now writing my own in Python and wxWindows to make it cross-platform. If anyone is interested then I'll post a link when I get to a usable state.

I would still like to get a like to a good alternative in the mean time.

The two I bought work fine with just a male/female 9 pin DB-9 cable. The software allows you to select between using Com 1 or Com 2, these have to be active in the computer to function.

I happened to use some Harris IRF-510 parts recently in my building
of the WA2EBY FET power amp design. I have had no evidence of
instability so far operating on 40m only. One would expect that the
Harris and International Rectifier parts would be essentially
identical. Further, I believe I remember reading some industry news
item some years back, announcing some sort of second-sourcing
agreement between the two companies. The Harris parts should
be, in other words, 'authorized'. BTW my parts have the Harris logo
rather than the letters HAR, but I would agree with the guess of
Harris as the manufacturer. I got my items from Dan's Small Parts
and Kits:
http://www.fix.net/dans.html

There is a brief writeup of my experience with the FET power amp
and a couple of photos at:
http://www.angelfire.com/md/k3ky/page60.html

737. Rocket Antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-01-31 23:03:09 UTC
From: steve@btinternet.com
Message-ID: <3a7896cc.11410486@news.btinternet.com>
Source record: 55034

Hi Chaps,
Appart from Ham radio I also do amateur rocketry - I'm making
an all aluminium rocket of about 1.5" diameter. The Rocket will carry
a small 70cms transmitter for tracking. I'd like to use the aluminium
body of the rocket itself as the antenna. Two possibilities occur to
me:-

1) isolate two sections of the body and feed like a dipole.
2) Make a sort of internal gamma match

See a diagram of the two designs at:-
http://www.btinternet.com/~rocketry/ant/ant.gif

The diagrams show a cross section through the rocket - nosecone at the
left. 1) is at the top 2) at the bottom.

While 1) seems to be shore fire I'm tempted to try 2) because I think
it would be a physically stronger. Would 2) work?

I can vary the body length to get 1/2, 3/4 or full wave resonance.

Any comments would be appreciated.

Can anyone explain how gamma matches work - I assume they transform
the feeder impedance to a higher impedance that is tapped off part way
up the dipole?

Hello Richard,

Has anybody tried different frequencies to the half way pilot? After all the audio is not just one frequency and it certainly does not know what the pilot frequency is. The whole idea of the pilot being in the middle of the audio band seems to have no mathematical basis that I have seen. Nor has the folding concept been shown mathematically to have any credence that I have seen.

Regards,

Although it's not a Smith Chart program per se, Serenade SV, the free-for-the-downloading student version of Ansoft Corporation's Serenade Design Suite (the full version of which includes linear and nonlinear circuit simulation, system simulation, layout and filter synthesis tools), includes Smith Tool, an interactive, Smith-Chart-based matching-network synthesis program that can be invoked from any polar graph produced by Serenade's circuit simulator. You can download Serenade SV's two (large) component files (SerenadeH.exe, which installs the circuit simulator that includes Smith Tool, and SerenadeS.exe, which installs Serenade SV;s system simulator) via the pages that begin at

http://www.ansoft.com/about/academics/sersv/index.cfm

And you can read more about Serenade SV in the January 2001 issue of ARRL's QST magazine.

Best regards,

Message-ID: <3A78D481.9EC2818F@att.net>
Source record: 55040

Seems you have the basic idea. I have never tried an internal gamma.
It may work, but may also interact with the tubing???

I you use the insulator version and a 1/2 wave rocket, you might try a
1:4 balun to help the match.

In either case, Iwould well shield the transmitter. Also if more han
a few hundred milliwatts are used, beware of hi-Z generated arcs vs.
rocket motors when testing.

The gamma:
In simplistic terms, an using a 1/2 wave driven element of a yagi (or
rocket tube) for example...

The center of the 1/2 wave yagi driven element is at low to zero
impedance (therefore we can use a metal support boom at the center).
The ends of the element are very high impedance (exact value depends
on design). Assume the feed coax is 50 ohms. Some point along the
length of the element, between zero (center) and very high impedance
(end), is 50 ohms. The trick is to hook the coax shield to the zero
center point and the center conductor to the 50 ohm point on the
element. The catch is that when you run the center conductor out to
the 50 ohm point (the gamma match rod), inductance is added. To cancel
this inductance a series capacitor of the same reactance is added.

FWIW... I have also experimented with rocketry. A different era.
'Twas back in the mid 60s when I was in high school. Was a member of
SOLAR (Society of Lyncburg Amateur Rocketeers). No commercial stuff
then. All total homebrew - which I still had some pictures. The
rockets were Al irrigation tubing. The small ones were 1' diameter x
3' long. The mid sized were ~1.5" dia x 6-7' long 2 stage with 'chute
recovery. The biguns were 3" tube 12' long. ZOOM!!!! We lost one big
one on the other side of a mountain range. We had a railroad tie
blockhouse and two remote tracking theatolites (how the hell do you
spell?) with sound powered phones to the blockhouse. Rockets were
fueled by zinc dust/sulfur mix and fired using electrical ignition
with safety interlocks. Safety was important and we never even had a
close call, but our sponsor (JayCees) departed company after seeing
our first launch :). We kept going on our own until we were noticed
by Washington DC air control radar and the FAA shut us down (we lasted
~3 years). The highlight was beating the Navy Polaris to the punch by
a few months... We launched a 6 footer from the bottom of a farm
pond. The top of the launch tube (sealed 12" PVC pipe) was about 2-3
feet below the surface. One of our club members got a summer job
offer at Cape Canaveral out of that!

Hi, do you think it would be possible for me to transmit 2 digital signals using a stereo FM kit (ie Veronica, etc.)? I suspect not. If this is in fact the case, could anyone please suggest a method that I could use to transmit digital information. Would I need to convert it to analog and then back to digital using DACs/ADCs?

Thanks in advance.

Dan.

Barry:
Thanks for this good information. My bottle of Q-dope always dries out long before it is empty, and usually can't be opened.

Question: You said "polystyrene" peanuts. Are they the same matereial as what are almost universally known as "styrofoam" peanuts, or they the more rarely seen tough, spongy pellets that appear to be cut off pieces of rod?

Also: Can one thin commercial Q-dope with acetone to prevent it from drying out? I keep a pint of acetone on hand. Or should I go looking for some Tolulene?

Every "Large lab glass vial" that I ever saw was Pyrexï¿½ glass, which is what is (was) used by Eimac for the envelope on their high power amplifier tubes. I'd expect, then, that Pyrex should be OK at RF, right? For sure you wouldn't want to use some leaded glass for a former.

Dan,

For a good answer, I think we need more information on your project. What is the data rate of your signals ? What is the distance between the transmitter and the receiver ? And more generally, could you give more details on the application ?

regards

Well, "tried" is very much the operative word in this case. But perhaps it is just the case that we are supplying two different interpretations to "just short of oscillation point". I take this to mean some feedback amount close to but below 1/gain -- let's say e.g. 0.99/gain. In this case do you maintain that two circuits of different physical Q will behave identically, or simply that their different Qs will both be multiplied by some similar factor? If you maintain the former then at what feedback < 1/gain do the dissimilar Qs become identical? OTOH, if you just mean that there is *some* feedback for any physical Q that can produce an arbitrarily larger Q+ then I agree with you. In practice, though, the user can't move the regen control in infinitely smaller bits to find that point, and the circuit isn't infinitely stable, so in practice I think we have the first case of feedback = (1-e)/gain, and the two effective Qs will be different due to the different physical Qs of the two circuits.

Drip some fresh solvent into the bottle-cap threads. This
often softens the dried plastic.

> Question: You said "polystyrene" peanuts. Are they the
> same matereial as what are almost universally known as
> "styrofoam" peanuts, or they the more rarely seen tough,
> spongy pellets that appear to be cut off pieces of rod?

The crunchy kind. Styofoam is just one trademarked name
(Dow, I think). I usually use the generic names since when
I worked in the chemical industry and wrote reports, I was
taught to avoid using such trademarks and copyrighted
names.

> Also: Can one thin commercial Q-dope with acetone to
> prevent it from drying out? I keep a pint of acetone on
> hand. Or should I go looking for some Tolulene?

Look on the bottle to see which solvent is currently being
used. You will have better luck thinning it with the same
solvent. Recognizing which is used by smell is second
nature to me, but thinking about it, I find it hard to
describe either smell. To me toluene smells sweeter than
acetone. Since you have acetone, you should recognize its
smell. Polystyrene is somewhat more soluble in toluene than
it is in acetone.

I generally recommend acetone as a good, general purpose
solvent for many applications because it is far less toxic
than most others. It is generally considered about the same
toxicity as isopropyl alcohol. It is a good polar solvent,
where toluene is non-polar. For general degreasing, where a
non-polar solvent is desired, I usually use painter's
naphtha (or Stoddard solvent, the main ingredient in WD-40,
which is a highly refined kerosene distillation cut).

All of these are very flammable, and while acetone and naphtha are not terribly toxic, toluene is fairly bad. It is best to avoid breathing the vapors of any solvent. So work in a very well ventilated area and use safety glasses. If you need to wipe something down with a solvent-soaked rag, wear protective gloves. The nitrile (Buna N) gloves are generally best with solvents.

AFAIK,the open 1/4 wave cable is a short circuit for the concerning frequency.Though he should take the frequency of the tv-channel for the 1/4 wave calculation.

> For sure you wouldn't want to use some leaded glass for
> a former.

Most large pieces of laboratory glassware are borosilicate glass (Pyrex is one trade name). It can take much higher temperature than "soft" glass. Receiving tubes generally did not use the "hard" glass of transmitting tubes. Glass has a fairly large dielectric constant, and its loss tangent is nothing to brag about. As glass heats, it can become quite conductive. Microwave printed circuit boards are made with quartz fibers in Teflon rather than glass to keep down losses and lower the dielectric constant.

If you have any Aquadag (colloidal graphite) like that used to coat picture tubes, you can easily demonstrate that glass is an ionic conductor. Get a piece of glass rod a few inches long. Wrap two pieces of bare copper wire around it separated about an inch. Coat the wire and glass with Aquadag to hold the wire in place. Connect the wires to an ohmmeter and heat the glass between the wires with a propane torch. Long before the glass softens, you will see its resistance drop. By the time it is at "red heat", it is

conductive enough that you can sustain its heating by passing current through it. Many glass furnaces are started with gas heating, but switch to electrical Joule heating one the glass becomes conductive enough. The relationship between temperature and resistivity of glass is known as the Rasch and Hinrichsen law.

Often in high power, high voltage tubes, you can notice a gradual coloration (usually brown or blue) with use around some of the leads coming through the glass. This is usually not de-vitrification but electrolysis and ion migration in the hot glass.

However, going back to regenerative receivers at HF, I would not worry too much about glass, ceramic, or most plastics. Medicine bottles make excellent coil forms.

Could a slot aerial be used instead? (ie Feed a slot in the aluminium).
Just a thought. I've had no actual experience with slot aerials.

Thank you for your input.

Could you tell me where the above FET pa article is published?

I have used two of these FET's in Fritz Raab's class-E pa and have also
had good results.

Thank you also for the URL's.

It depends on what you want to use a Smith Chart for.

If the purpose is design or analysis or performance of transmission lines with given terminations, or computation of what the terminating impedance must be for a given input impedance, then small professional-grade programs are available from the website below.

They are much more accurate, faster and easier to use than charts. They cover the whole electrical spectrum whereas Smith charts are useful at only at HF. Also transform from series R+jX to parallel equivalents, and reverse. Smith charts are obsolete in this new Century.

Download in a few seconds each, programs RJELINE2, RJELINE3, COAXPAIR.

Not zipped up. Run immediately.

Rolie
OK on being in WA - we should met as there dont seem to be too many
"serious" experimenters in WA
the rational for the subcarrier at 1750 Hz is that it is approx half
way between 300 and 3000 Hz. I think the folding analogy does make
sense - I thought I understood it all at one time.

I seem to remember a warning on the last can of Acetone that I bought warning that it may be a liver carcinogen (I'm not sure whether this is due to the Acetone itself, or due to a contaminant in it). In any case, please be sure to read and heed all appropriate warnings on the container. Additionally, it may be worth obtaining a MSDS on the chemicals in use.

Message-ID: <ttie6.54011$_8.1676578@news1.rdc1.bc.home.com>
Source record: 54960

The data rate is negligible, on the order of bytes/s. I will likely however need to send 2 or 3 of these digital streams. The range need only be a metre or two at most. The application is for transmitting positional data from an optical encoder. The optical encoder will be on a moving (rotating) object which makes the use of a wire lead very difficult. The rotating object will have a free range of rotational motion so any wires could get snagged or tangled and restrict motion.

Ideally I'd like to be able to build this out of readily available parts, and it shouldn't cost outrageous amounts.

Thanks for your reply, I'd really appreciate some suggestions.

Dan.

> Why do you say Smith charts are only useful at HF??? Please explain.

Actually, I believe he went on to write that they are "obsolete". Mind you, there are those of us who don't share that opinion. In fact, my Smith chart seems to work just fine at audio frequencies...and hasn't failed to work yet when I've called on it in 2001. To me, it remains a valuable visualization tool which helps me anticipate what will happen when I add or subtract elements in a ladder network, or change their values, and with a computer-aided chart, there's absolutely no sacrifice of accuracy. (Note that it's easy to read a paper Smith chart to the accuracy needed for a great many engineering applications, and it's easily powered by a brain and a pencil in the field.)

As with any tool, if you don't find it useful, don't use it. But don't assume it's not useful to others. A bit like "proving" that a bumble-bee can't fly??

I agree with Reg, if numbers are what you want. There's nothing more frustrating than playing the geometry-construction game on a paper chart, and watching the drawing errors mount up.

On the other hand, Smith charts are wonderful as a thinking tool. Don't think of it as a calculator - that really is obsolete - but simply learn to read it like a map.

There are about six things you need to know in order to read a Smith chart like a map, but words are the wrong way to teach something that is essentially visual. Find out more if you can - you won't regret it!

The ideal software is something that gives you the accurate numbers *and* the intuitive graphical features of the Smith chart too. One Windows program with those features is Z-MATCH marketed by Number One Systems, UK: http://www.numberone.com/ds_zmatch.htm
The only problem is the "professional" price.

Your 813 comments are interesting, Skipp- especially the part
about running nearly 4KV on them. I would love to hear a bit
more about how you are running them- the highest band you
have run with 4-813, what kind of plate current, what kind of
power output you have seen, etc. Oh, yes- and what modes?

I have two HB GG 813 amps here with pairs of tubes. One runs
with a very stiff 2500V supply, and typical output is around 7-800W
cw. The other amp has a very poorly regulated supply, idling at
~3300V and running about 2500V key down. Power output is
similar. From what I had read over the years, I thought I was
pushing it at 3300V. Just wondering what your key up and key
down plate voltage runs.
Thanks, 73, David K3KY
P.S. I cool both of my amps with ~100cfm muffin fans blowing
across the envelopes and plate caps.

The Smith charts in programs such as ARRL Radio Designer and Harmonica are very useful for designing amplifiers, oscillators and matching networks using L, C and xmission lines in a Z0 system environment. The ability to get gain, stability and noise figure circles and the input/output reflection coefficients that provide the desired performance over a wide frequency range is hard to duplicate using nothing but equations. The visual aspect adds insight that is almost impossible to get otherwise.

There is a two part QEX article for the Radio Designer program that is available from the ARRL QEX website.

Hej Lasse,

I still think dual mixers is the easiest way to do this. Mini-Circuits
have suitable components. If you need precise quadrature, a fixed LO, a
power splitter, and two pieces of coax differing by 90 deg , each feedind
a mixer combined with a VCO
feeding the RF port of said mixers at 0 deg difference. Assume first LO of
1000 Mhz, VCO of 1020 to 1140 Mhz will give you 20 - 140 out of the mixers
in quadrature over a wide range. If you dont like cutting coax, use first
LO of 2000, divide with two FFs and you have 1000 out with 90 deg
difference

If the tuning range had been narrower, you could have used a PLL.
The characteristic of the mixer type PLL is lock at exactly 90 deg diff.

If there is any level info in the 20 - 140 mhz signal, then the mixer
version
will preserve that.

Gullik

Yeah, when I was a kid I personally made it a point of honor to break as
many of those rules as possible. I never managed to get a bird hung up
in a power line, so that one still bugs me. Besides that one, I believe
there was one other safety rule that I never got around to infringing,
but I can't remember what it was. :)

Acetone is listed as being non-carcinogenic by NTP, IARC, ACGIH and OSHA. I used to work for the company whose long history of safely working with acetone convinced the EPA to remove it from the SARA 313 list (Eastman Kodak).

Like most solvents, acetone can certainly harm the liver and kidneys. Just as it is a good degreaser for cleaning parts, it also dissolves the fat from cells in the liver and kidney. Skin dermatitis may result from this same action on the skin. This is the reason I suggested the use of Nitrile gloves, safety glasses, and working in a well ventilated area. As I noted, acetone is similar to isopropyl alcohol in its toxicity. Drinking an ounce will probably not kill you (but the hangover and other nasty effects may make you wish it did). Ethyl alcohol (ethanol - the drinking kind) will also de-fat your liver and kidneys, and also cause intoxication and brain damage.

But if you compare the toxicity of acetone, isopropanol, and ethanol to commercial brake and carbureter cleaners, brake fluid, antifreeze, gasoline, etc. - you will find them to be pretty tame in comparison. This is not to say you should treat them as harmless; it merely says you should treat the other materials with considerable care.

You sure can do it.
Your digital signal need a "1" or ON state and a very distinct "0" or OFF state, so use a 1200Hz tone for zero bit, and 2400Hz tone for the one bit. This methode was used for the old tape drives (remember them?). After you run your origonal signal into a digital signal then use that as a control to generate the 1.2kHz and 2.4kHz. Send those into the input of the xmitter, and all is good from there. To return the two tones to digital signals so that they can be send through ther DAC you can count zero crossings, and the rest I leave to you.

If you can find the book "Computer Peripherals that you can build" the general diagrams are in there.

I've actually been trying to download these for a couple of days. I got serenades.exe, but I couldn't get serenadeh.exe. I kept getting a 124k file then the download would end even though the page showed that it was a 31meg file. I just tried again today and the page now shows the size as 124k, but when I run it I'm told that it isn't a valid program. Any thoughts?

I think I would consider sending your 2 channels alternately (time division) or do something to make sure the state changes on the 2 channels don't happen at the same time. Given your low data rate, shouldn't be a problem.

I'm suspecting that with digital signals like that you aren't going to get real good channel separation, so some other way to split your channels would be good, or perhaps give it a little help. Either case would make the receiving circuitry a little more complex, but at least it isn't the moving part.

Depending on your sensors, I'd be more inclined to use a PIC to generate the tones, this also gives you some flexibility in multiplexing etc. and the circuitry is likely to be a lot simpler. Also, the PIC is a pretty low power device and your power supply will also need to move along with the sensor, so I suspect the lighter the better.

Perhaps an even simpler approach is to use the PIC to key an oscillator and use some sort of on-off code, rather than tones. You would need some sort of computation on the receiving end in any case, and a little Epson oscillator can be had for $3. It's probably way smaller than your FM transmitter, and it and the PIC can be run for days off a 9 volt battery. Your receiving setup would be a little different, but still not rocket science.

hi,

I just finished building my first QRP rig; heck, my first transceiver of any kind. I am so excited that it works; I'm thinking of places I can take my radio now, where I couldn't before.

We always take our vacation on the beach each spring (Nag's Head, NC) and I wondered about operating from the beach. I fly there, so bringing supports such as a mast is not really an option. Bringing a roll of thin wire for a 40m dipole wouldn't be so bad, though. But then what would I do with it, just lay the dipole on the sand?

Anyone have any better QRP beach antenna suggestions?

tnx,

Interesting, thank you. I can't envision any method of transmitting or receiving data, since it's not my area of expertise but I can see how that would be pretty easy to implement with a programmable microprocessor or PIC or something of that sort.

Thank you also for the book title. I'll try to find it at my university library.

Dan.

Hello,

Is there anybody out there who could help me with the pin-layout of a not too old octal base Valpey type VCO-2 100kHz (sealed in a blue color 5.5cm high metal cylinder) cristal. I suspect it contains a heater element as well since a temp = 75°C is mentionnend as well.
I am looking for a page on the net who could give me a typical application diagram as well? I intend to use it as a reference oscillator and the type of oscillator circuit to be used.

Thanks

Andre / ON7UM

Martin, K7MEM, replied to me personally by email with the same message, and I replied back to him privately. Yes, his was a very thoughtful and informative message. One of very few.

I've been very active in the aviation newgroups, where anyone can ask any question at any time, and information and advice is freely shared.

I've been around long enough to have met all sorts of people. There are always those whose knowledge gives them an air of superiority. I guess they forgot that they started from square one, too.

Actually, that's why I posted in the first place. A local ham was recommending, actually pontificating, that a builder must have this, and that, of that brand, etc, etc. It seemed to me that most builders with experience (and a budget) have learned what's essential and what's not.

Thankfully, there are good folks like Martin. I now have my workbench "equipped" with what I need, and have learned to solder well enough to build a kit (I hope ... grin!). I'm not a "brand new" ham, licensed since '92, a shack full of Japanese radios, yard full of antennas, etc. But the Heathkit era was over before I came along in radio and I've never built anything more than dipole antennas, and never soldered anything other than connectors and water pipe.

I've also met several very helpful hams on 30 meters, who, at the mention of building a QRP kit, were ready to offer plenty of practical advice.

"I won't live long enough to make every mistake, therefore I resolve to learn from the mistakes of others"

==========
Background -

Smith did not "invent" Smith charts so much as simplify much older charts which had been in use even before the end of the 19th century to solve power and telephone transmission line problems. And indeed a wide variety of problems in other engineering fields.

In mathematical terms, the old charts provided a graphical means of performing extremely complicated and tedious calculations involving complex hyperbolic functions. Amonst other uses they solved equations such as Tanh(A+jB) = X+jY which occur very frequently in the analysis of performance of all transmission lines.

Before the age of computers they were absolutely essential labour-saving tools. They were faster than slide rules, trig-tables, log tables, etc, but not so accurate of course. They consisted of a whole stack of charts and were still very cumbersome to use.

When in the 1930's many transmission engineers were shifting attention to carrier telephony, HF world-wide and VHF radio, etc, it was realised the old graphical aids could be simplified and greatly reduced in number by assuming the characteristic impedance Zo of HF lines to be a pure resistance Ro, the reactive component jXo of real lines in many cases being small enough to be ignored. This, for example, reduced hyperbolic functions to Sin(A) = X and InvSinh(A+jB) to Log(x), with corresponding simplification of charts.

Smith, around 1940 I think, then an employee of Bell, was the first person to have the newly simplified charts printed and his name attached to them. They were quickly snatched up and put to use in the design of ground and airborne radar systems. After the war came TV.

One consequence of setting the angle of Zo to zero is to imply that conductor loss per unit length is identical to dielectric loss per unit length - which it never is ! On the other hand this does not begin to matter until a line is long enough for the actual loss to be noticeable. Radio amateurs are concerned only with short lengths of low-loss lines. There are other consequences.

The exact formula for Zo is -

Ro+jXo = Sqrt((R+jwL)/(G+jwC)) ohms.

So Smith charts can be misleading and inaccurate unless w = 2*Pi*F is large enough to make

Zo = Sqrt(L/C). ie., a lossless transmission line.

But the angle of Zo of real lines approaches -45 degrees at power, audio frequencies and VLF

Similar discrepancies occur when considering velocity. Smith's lines always have a velocity factor of unity but, of course, it is easy to apply a correction if it is remembered a correction may be needed. But even the correction is guesswork.

A Smith Chart is incapable of showing how an SWR as high as 2.414 can arise. According to Smith an SWR greater than unity is impossible. Beware of using his charts as educational tools.

The sentiment attached to Smith Charts is understandable. But in the age of the PC the young busy engineer has tools of exact precision, labour-saving in the extreme, and covering all frequencies from 1Hz to 1GHz. And just as educational.

I have a book of 6-figure mathematical tables. Also a beautiful 12" slide rule in a pigskin leather carrying case, with a strap for attachment to the owners belt, in excellent working order. Ocasionally I take it out of its drawer and handle it for a while with fond memories.

But I never use it.

And in 57 years of association with transmission lines, from 0.1 Hz to 3 GHz, I have never used a Smith Chart either.

Hej Gullik
The use of mixers are not really possible (or desirable) in this case!
The 90 degree phase-shift is to produce a Butler matrix for beam
forming i.e. in a direction finding system. Due to the wideband
performance of the antenna the mixers will severly limit the dynamic
range of the antenna!

Using simple phase-shifting filters will give me 1 degree accuracy and
uses only simple passive components.

Next step will be to synthesize the phase shift digitally, using 4
receiver channels rather than 2 or 3 as used today.

Thanks anyway for you taking the time
Cheers

There is probably something wrong in your achievement. The drift of a well designed Colpitts oscillator is about 1/1000 of the output frequency, i.e. 60 kHz in your project. You can even get 1/10000 short term with special thermical and mechanical care.
So, check the design, and specially the bias of the oscillator transistor. Do you use a buffer ? It's important to isolate the oscillator and the load.

I don't understand very well your project. The ordinary FM receiver are designed for wideband FM (the channels are about 200 kHz wide). If you use such as a receiver for narrow band receiving, the results will be very poor.

good luck !

Very interesting web page, very cool. I like the relative simplicity and
economy of using only one good VCO combined with logic to divide out the
necessary frequencies. Of course, using a in-band IF is going to hurt the
IF rejection capability but 10.7MHz isn't likely to have strong signals.

Did you pursue using a higher first IF (45MHz-ish seems popular in the similar
commercially-made receivers) and running a single VCO over the range of
45-75MHz? You'd have to locate a decent roofing filter at the high-IF but
I suspect little else would change appreciably in your front end.

The 45-75MHz synthesizer could dispense with the division logic, too. The problem
is that the loop 'N' would increase considerably if you run a single-loop, which
potentially degrades the LO close-in phase noise behavior (it depends on loop
bandwidth, the VCO quality and the reference quality). Have you considered a
dual-loop mix-down configuration?

Overall, pretty impressive! Very, very cool.

As you noted, Martin gave you quite a bit of good advice! I hope a couple more comments might help.

For soldering irons, I've been using Weller WTCP stations. I've gotten three of them (ok, ok, the last one is for spare parts if needed!) over the years, all industrial surplus and never more than $10 as I recall. If you find one in a surplus store, check it out. If the sleeve that holds the tips on has not been mashed by overzealous plier-wielding techs, and if you can pull the tip in and out and hear the thermostat clicking, and if you can plug it in there and it heats to melt solder within one minute, I'd recommend it as a good buy, especially if it's in the $10 or less price range. (NEVER use pliers to tighten the sleeve on these; the wonderful design works fine finger-tight.)

I agree with Martin: digital or analog meter depends on the use and personal preference. But you can get some really cheap ones that are quite servicable. Radio Shack, mpja.com, and Harbor Freight all come to mind. You may eventually decide that a full-featured digital meter is the way to go, but save that for a while.

There are some really, really handy things you can build for yourself. I have a circuit tracer I designed and built 25 years ago that's still wonderful to use. (I really should post an article on it sometime!) It won't turn on semiconductor junctions, and can distinguish by pitch the difference between a short and as little as one ohm. Runs ten years on a single AA cell, no pwr switch. And it's fairly simple to build, about 5 transistors. Also, there are some wonderful little qizmos on http://www.techlib.com/, especially the "Curious C Beeper" at http://www.techlib.com/electronics/c_beeper.html. Poke around: there are other web sites with neat home-built gadgets helpful on the hobby bench.

Back before I managed to get some decent commercial equipment, I spent quite a bit of my hobby time building my own instruments. Some of it, I still use, like the circuit tracer. Other things that I'm glad I built and still use are bench power supplies. My feeling is that you can never have enough of those! But with LM317 and LM337 regulator chips, you can pretty easily build a 1.2V -to- 25V power supply, plus and minus. I find it especially valuable to have that range, plus something that covers logic circuits at maybe a bit more current. (Even a fixed +5V supply would do there,
until everything goes to 1.5, 1.8, 2.5, 3.3 and 5V!!). This may be getting into the holier-than area, but I couldn't live long at my hobby bench without some sort of scope and some sort of signal sources...if I

were starting all over with very low budget, I'd still be keeping my eyes open for a decent used scope. It's possible to homebrew some decent signal sources; all depends on what you decide is important.

Finally, don't overlook the possibility of donations. Over the years I've accumulated an awful lot of junque...things that are perfectly good for building with, but which I've come to realize I'm very unlikely to use. I'll bet there are lots of others out there like me. I would be quite happy to find a local struggling hobbiest that I could give some things to. I'd even make a semi-permanent loan of a very decent scope to someone I thought deserved it and could put it to good use. If you can find someone locally like that, you may also find an "elmer" or mentor in the bargain, someone that can give you guidance and save you from some of the blunders (but hopefully let you make enough blunders of your own that you learn from them. God knows, I've learned a lot from mine!)

Hope these are useful additional thoughts.

Cheers,
Tom

Panavise is really nice, but for alternatives at lower price, you might check http://www.mpja.com/product.asp?product=11240+TL. I have one of these, and while it can't do all a panavise system can, you might find it servicable. It opens to about 2 inches max. I'm sure there are other similar ones available, perhaps locally. (I also have a larger bench vise for mechanical things...this little one would not do for serious mechanical work.)

Bob.
Here is a copy of some info which I posted some time ago. It describes how to identify the pins of an unknown bipolar transistor. If you don't know which polarity the VOM leads are when measuring ohms, measure with another VOM - or practise on a known transistor. Any use??
Ian.

[Start]
There's a simple, old-fashioned method of finding out which (bipolar) transistor lead is which. All you need is multimeter (VOM) set to measure resistance (I use my trusty AVO) and a wet finger. IMPORTANT NOTE: You also need to know what polarity the test leads are when you are measuring resitance (the AVO red '+' voltage lead is NEGATIVE, and the black '-' voltage lead is POSITIVE. Not all meters do this).

First, you need to identify the base. Assume that you are going to measure a good NPN transistor.

A transistor is essentially two diodes, back-to-back. An NPN transistor looks like this --|<|>|-- , and a PNP like this --|>|<|-- .
c b e c b e
The base-to-collector and base-to-emitter connections will give the usual 'forward biassed diode' (should be low resistance) with the meter connected one way round, and the 'reversed biassed diode' (should be open-circuit) the other way round. Connect the meter between pairs of leads in turn and find the lead which is 'common'. This is the base.

You next need to find out which of the other two transistor leads is the collector and which is the emitter. For an NPN transistor, connect the meter POSITIVE lead to one, and the NEGATIVE to the other. The reading should show a high resistance. Now apply a wet finger between the positive lead and the base. This applies forward bias to the base, the transistor now conducts, and the resistance drops to a relatively low value (note that the wetness of the finger and the pressure applied affect the reading!). Now reverse the meter and again apply the wet finger from positive to base. Note which way round gives the lowest meter reading. This is when the meter positive lead is connected to the collector. You have now effectively identified all three transistor leads.

For a PNP transistor, the same method applies, but the meter will be the other way round. If the meter readings are not as expected, you will also be able to find out if the transistor is faulty (eg O/C base-emitter, S/C collector-emitter, etc).
[Finish]

A number of folks have suggested a DMM - I would disagree.

It's pretty rare that you ever need to measure something to more than 2 significant figures, and that is easy to get from an analog meter. On the other hand, you frequently need to asjust something for min or max, and that is a lot harder on a DMM than on an analog meter.

The key thing is to get a meter with a high input impedance. Almost all DMMs seem to have an 11 Meg input impedance which is nice, and turns out to be a convenient number, too. You may have to hunt around a bit to find an analog meter with a good input impedance but it's important.

Somewhere along the way of your first few kits, you will also want an RF probe. This is something you build, rather than buy. Exactly how you build it depends on the meter you are plugging it into, so even if you can't come up with an 11 Meg meter, at least get a meter you KNOW the impedance of.

I have a bunch (more than 30 left) of Solitron Microwave part
SF1132-6001 SMA to N bulkhead receptacle. These are NEW OLD STOCK,
still sealed in the little plastic bags. Datecode is 7913. These cross
to a Pasternak Enterprises part PE9104 which they sell for $35.95.

There's a photo at:

http://novatech-instr.com/Ebay_Images/dscn0148.jpg

Let me know how many you want and make an offer. Last sale was about
$8 each. These need a better home than my "J.B."

Thanks.

Steve.

I'd agree with you about the need for seeing a peak over a precise value,
but I think I'd still aim someone towards a DMM.

One reason is that DMMs have become common, just as in the old days you
could get a crummy VOM in all kinds of places. You can get a simple DMM
at the local Radio Shack or hardware store, and you can get it for under
twenty dollars. You may have to hunt for a VOM, and I suspect that it
will cost you more. Remember, those low end VOMs that were available
everywhere were often not so great, while the design of the DMM probably
ensurs that it loads the circuit under test less.

Probably someone dosn't want to stay with a $20 DMM, but it gets one
started, and the experience of using it helps the newcomer to evaluate
what they actually need before spending big money.

I think the prime reason I'd suggest a DMM over a an analog meter is
the memory of my first meter. It was a VOM, probably not completely bottom
of the line, that someone gave me, complete with the back missing.
I kept forgetting to change the switch, and soon the needle was bent
a bit from either leaving it in the ohms position when reading voltage,
or not setting the voltage range high enoug. It didn't take that
much longer before the meter was bent too far to make the VOM useful.

That won't be happening with a digital meter. An overvoltage, especially at transistor levels, will not be damaging to a digital meter. And while I suppose the low end ones may lack them, the fuses in DMMs have saved my meters a number of times.

That leaves the issue of peaking. ANd that could be one of the simple first projects that someone tackles before building a complete transceiver kit. Some surplus meter, even a tuning meter out of a "stereo" receiver, and op-amp or two, and some resistors, and you've got a simple equivalent to a VTVM. It lacks a scale, but then you have the DMM for that, and what you want this meter for is trends.

This sort of thing has appeared in some handbooks, it is in the 1993 edition but not the 2001. And the idea is in "Solid State Design for the Radio Amateur" which is still a great book for someone interested in this sort of thing, though the meter shown could be improved with more recent, and higher input impedance, op-amps.

It is somewhat more toxic than acetone, but still less dangerous than the chlorinated solvents or aromatics (benzene, toluene, xylene). It is not considered a carcinogen. The odor of MEK does not bother me too much, but the odor of methyl isobutyl ketone can give me a headache within minutes.

As a comparison, the permissible exposure levels and short term maximum exposure levels for acetone and methyl ethyl ketone (MEK) are shown below:

Acetone Methyl Ethyl Ketone
OSHA PEL 1000 ppm 200 ppm
OSHA STEL 300 ppm
ACGIH PEL 750 200 ppm
ACGIH STEL 1000 ppm 300 ppm

OSHA - Occupational Safety and Health Administration
ACGIH - Americal Council of Government and Industrial Hygienists
ppm - part per million (by volume in air)

Thanks Tom for correcting my slip of the tongue (pen, keyboard).

Yes, it is the Reflection Coefficient which the Smith Chart asserts cannot rise above unity whereas on real lines the RC can approach 1 + sqrt(2).

Would you be one of those chart worshippers who disagrees ?

Hi Reg,
I'm not a chart worshipper, but I do appreciate the fact
that when I draw a curve on a Smith chart, the chart shows values
at an infinite number of points between the ends of the curve.
No digital computer can do that. Of course, computers can draw
curves, too, which are good enough, but if you measure the time it
takes to turn on a computer, load the software, enter the parameters,
and click the mouse, you'll find you haven't saved much time over
just reaching for a piece of paper and drawing a curve on it with
a compass.

Francine, I've nothing against Smith's transmission line charts except their limitations. They've proved their worth over the last 60 years. But, as with any other tool, users should understand or at least be very aware of the limitations.

Here's another one: It can arise that least loss on a line does not occur when the line is in a matched condition. But any analysis method which makes the same assumptions as Smith's simplifications will give no indication of this.

Your habit of calculating first and then checking by an alternative, independent, graphical method is what I have done myself on countless occasions. If both answers fall in the same ball park then all's right with the World. If not - then panic stations.

Incidentally when RC = 1.5, SWR = -5 (minus 5). ;o)

you could use a 15 or 20MHz xtal osc to injection-lock it with loose
connection (small capacitor), or simply use xtal oscillator on 60MHz

I have often seen 60MHz xtals available as surplus, but believe they
are usually readily available low price xtals at electronics dealers

Assessing loss in coil formers (from, I think, RSGB RadCom 'Technical Topics' some time ago....

Put the intended coil former in microwave oven. As microwave ovens don't like operating with no load, also put in a small cup of water. Run the oven for a short time (say, until the water is nearly boiling). Now feel the former. If it is still cold(ish), then the RF losses are small. If it isn't, they aren't.

73,
Ian.

From: JD <dyson@jdyson.com>
Message-ID: <F70f6.189$c5.133510@news1.iquest.net>
Source record: 54914

For small signal (and very inexpensive cost) my stash includes:

Medium/low noise at medium impedance, good for video:
2n3904 (npn), 2n3906(pnp)

Medium/low noise at low impedance, larger geometry than above:
2n4403(pnp)

Medium/low noise at higher impedances
2n5087(pnp), 2n5089(npn)

If I was stranded on a desert island, and could have only one transistor,
for an NPN, I'd pick a 2n3904, for PNP, I'd pick a 2n3906. They don't have
the best noise characterists, or the highest ft... However, they don't have
any real handicaps either. They seem to work fairly well balanced in
characteristics. The 2n2222a/2n2907a are also good, but the "standard"
versions are really metal.

Our rockets were ballistic. They left the launch stand with a calculated 10 to 15 Gs acceleration - usually going where they were pointed*, but not reaching escape velocity. Fuel was exhausted in just a few seconds. I shot a rocket in the air, It came to ground... I usually knew where :) We calculated the acceleration by filming (8mm) the launch. Knowing the field of view and the frames/second we could calculate the average acceleration over that distance (maybe ~300 m). It was probably even higher at take-off - We never launched any animals!

*We once had a timing malfunction on a 2m long one. The second stage fired when pointed down. Burried itself several feet into hard, dry red clay!

Hello and thanks

I am looking for transistor data for a TRW PT4236c
it is in the RF power amp stage of a 70Mhz PMR radio
and I am looking to cannibalise the PA strip to use on 50Mhz
(6m Amateur Band).
Can any one point me to a URL with the data or have you got
a data sheet.

Thanks Martin

In the remains of a power supply unit I have are a number of Delco ,type DTS 401 transistors.

According to a reference database it is a NPN type transistor in a TO 3 enclosure (like the well known 2N3055) . Its application is stated as : line deflection.
Question : What is the (max) rated current for the device.

The intended new application is that of an electronic shunt for a 12 V lead-acid battery system charged by solar panels and a wind driven generator.

TIA for any advice

829. Homebrew Newbie, Transmitter Design.

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-04 16:34:04 UTC
From: Michael Ransburg <daneel@tux.org>
Message-ID: <95k09s$312$1@nnrp1.deja.com>
Source record: 54924

Hello!

I'm a homebrew newbie. I built some of the kits available from quasar electronics and other kit selling sites (mostly fm transmitter and receivers) and I learned a lot from this. I think I know how a transmitter works in theory, but I still have problems to match the things I know with what I see on the circuit board (so...where _do_ we have the oscillator here...?).

Let me give you some ideas of what I pretend to know already. Please correct me if something is flawed, I appreciate it _very_ much.

To build a transmitter you first need some power source. Then you need an oscillator which resonates at a specific frequency, depending on the inductor (coil & core) and the capacitor. The + plate of the capacitor gets charged with electrons by the power source. Once loaded it will start to discharge through the inductor, causing it to build a electromagnetic field holding the power of the capacitor. As soon as the capacitor is discharged, the em field will collapse and the power of the field will flow to the other plate of the condensator and the game will start again. I can imagine that this causes the amperage to raise and fall continously, is that the sinus wave?

Ok, so you got a continous raise and fall in amperage, this occurs with a given frequency, the frequency we want to transmit on. It's just a sinus wave without information at this point, so we get an electronic microphone hooked up to the circuit. Such a microphone is some sort of condensator. I'm not sure how it works exactly, but I guess it converts noise into amperage in some way, so we got the same as with the oscillator above, only that this wave contains information.

Next step is to modulate this wave onto our sinus wave (depending on what sort of modulation you use this happens by changing frequency or amplitude) and send it to the antenna which will radiate the modulated wave as electromagnetic waves.

Ok, this is my understanding of a transmitter.

I know how transistors, resistors, condensators and so on work - in theory.

I found a very simple fm transmitter schematic here:
http://www.aaroncake.net/circuits/fmtrans.htm

I tried to find out how it works, but I hat not much success until now. I know that if I figure this one out, bigger schematics won't be such a problem anymore, because you always got the same components, just more

of them.

So, what I'm asking for is if someone can help me figuring this schematic out, or another one of a transmitter if he / she prefers one.

I'll try to start with the one on the above url:

I find it easiest to look which way the power flows in the first parts of a seconds when connected, to establish the power circuit.

The power always flows from + to -. So it will first flow to the bottom of the schematic, where it comes to a crosspoint. Let's look at the left side first. So it will flow to the left, getting to the first resistor R5, flowing through it and getting to the collector part of Q2 and to the resistor R4. At the same time it flows through resistor R6 and charges the positive plate of C4. Some reduced amperage comes to the base of Q2. C4 acts as some sort of filter which will only let ac through (what exactly does that mean? I _suppose_ that it will only let the amperage waves produced by the mic through?). However, when someone speaks in front of the mic it will produce amperage waves / impulses flowing from the + side of the mic through C4 and amplifying the collector amperage on Q2. The amplified amperage gets outputted at the emitter of the transistor Q2 and flows to the minus pole of the battery, the resistor R2, the condensator C1 and the resistor R1. It is used at the base of the transistor Q1.

I guess the oscillator in this circuit is the inductor L2 and the condensator C5. So the sinus amperage comes to the collector of the transistor Q1 and gets amplituded by the "noise" of the microphone which is on the base of the transistor Q1. Is this the FM modulation process?

The modulated (?) amperage is outputted at the transistor Q1 and somehow gets to the antenna...I'm not really sure how this happens...

Ok, this is my understanding. I would be _very_ _very_ grateful if anyone could extend my horizon with some explanations, well documented schematics and specially with an explanation for the schematic I tried to explain above.

You should have an impression of what I know at the moment, so I'd be also grateful about book suggestions, if you can make one.

Thank you very much and sorry for the lengthy post... :)

cheers
mike

The 2N2222 appears to be slightly larger geometry, with higher capacitance,
but gain that holds out for higher currents.

The 2N3904 appears to have very slightly higher gain at low (up to 10ma) currents,
and is more 'nimble' (lower capacitance.)

Much of the high-current ability of the 2n2222(a) is lost, unless you have a
larger package version of it (e.g. TO-5), but for switching, the lower drop
at the same current can be useful.

The 2n2222 would be better balanced in linear applications for a >330mw package,
while the 2n3904 can use more of its 'useful' beta/ft current ranges within package
limitations.

For high-current applications, several parallel, emitter resistor balanced 2n3904
can often be used where a 2n2222 might normally be advantageously over the
2n3904. This application isn't desirable for low-offset switching though.

Both transistors are very useful devices, and even though they aren't quite totally
interchangable, they are very close to being so. My review of the two transistor
types is almost splitting hairs, because for the majority of typical benchtop applications,
the transistors are interchangable.

John

==========

Hi Ian,

It's hardly the ideal program when you get a precision version of the Smith chart plus 8-digit (?) numbers, complete with all the errors in the first digit which Smith built into it. At low enough frequencies the errors are orders of magnitude.

They who use such programs are liable to suffer from delusions of accuracy.

Do they come with a Government health warning on the package ?

As far as I'm aware, the only limitation that particular program shares with the paper chart is the assumption that the characteristic impedance of the line is purely resistive. Otherwise I believe it uses the full transmission line equations (including line loss) to compute its results. The chart format is merely for visualisation and optional input.

You may be almost unique in having spent your career in areas where the Smith chart *doesn't* work - VLF, very long lines and so on. Thus you've learned all about its shortcomings, but you say you have never actually used it to see what it *can* do. For the rest of us, it works just fine (or close enough) as a visual aid to *understanding* transmission lines and matching problems.

I agree with you that the days of the Smith chart as a calculation tool are over. I've tried lots of impedance calculators, and even wrote one of my own (http://www.ifwtech.com/g3sek/netcalc/netcalc.htm), but all they give me is numbers. They don't give me the *understanding* that a Smith chart can.

get a Radio Amateurs Handbook by ARRL..
most book stores have it..
or you can get an older one at a used bookstore..
the info is all in there..
other good pubs include any military, Navy , Air Force , Army on basic
electronics..
they have tons on transmitters, step by step...
another good one is Basic Solid-State Electronics by Van Valkenburgh..
you need to start with the understanding fo the basics and build from there
and you'll have fun..
if you miss the basic elements you'll struggle, sweat and probably give up
becasue you're not having fun..
good luck

2N2222A has better specs, but I can remember direct comparisons. I
almost always use the 2222 for just about every generic application that
needs a small signal transistor.

Well, if you want/need any more opinions or application/design
help with simple circuitry, I am willing to give you some help.

One thing that would be fairly useful to someone who wants to
start designing circuits, is a copy of spice. I happen to use a
personally compiled version of spice2g6 with whatever models
that I can scrounge up. I have the same version compiled for
NT/2000 and FreeBSD, and works rather reliably, with some undesired
personality (not perfectly) for my own use.

The commercial version are much better, and handle end conditions
better, since spice 2g6 has a certain amount of personality all
by itself!!!

Otherwise, for simple design advice, feel free to send messages, or
ask on the net.

John

2N2222A is better for higher currents, but it has higher capacitance. The 2N2222A has a (important) collector to base capacitance of 8pf, while the 3904 has about 4pf. The 2n3904 is a lower current part, and appears to be essentially a smaller version of the 2n2222... The 2n3904's Beta peaks at about 10ma, while the 2n2222a peaks at about 40-50ma.

I wouldn't agree that one is better than the other, but one is better in lower current apps, and the other is slightly better for higher current apps. The disadvantage of the one more optimal for higher currents doesn't normally have more power dissipation capability. In order to use the higher current abilities of the 2n2222a, you have to run it at lower voltage... Given this fact, except in low voltage applications, it is just as good to parallel and carefully current-divide amongst multiple 2n3904s.

True 2n3904's cost about 4-5cents each, but to get to that price level for 2n2222as, you probably have to find mps2222a parts. (When I buy transistors, I tend to buy in quantities of 100-500, since they are so very cheap now.)

The DTS-401 is a higher voltage, lower current device compared to the
2N3055.

DTS-401 specs:
max Ic: 2.0 amps
Vceo(sus) @Ic: 300v @ 100ma
hFE @Ic: 20-100@500ma

That's the basics. If you need more, contact me.

Obviously the program seller hopes to sell it at an inflated price by
associating it with the deserved popularity of the Smith Chart. A sales
gimmic !

But how ridiculous it is to deliberately spoil the ability of a computer
program by obliging it to conform to the technical shortcomings of an
accompanying status symbol.

848. 8950 Vacuum tube ???

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-05 11:16:14 UTC
From: mystique224@home.com
Message-ID: <3A7E8DE4.13E4191E@home.com>
Source record: 54944

Good Morning Everyone,
I am posting this unusual request because I had a customer bring in this piece of equipment the other day. It is a Ham series amplifier that uses three 8950 final tubes and 1 8950 tube as the driver. Anyway, all of the tubes are less than 30% on my tube tester. After some research, I have found that these tubes are extremely hard to find and when you do find some, they are usually used and very expensive. My question to you fine intelligent people is "Is there a replacement tube of similar characteristics that I can substitute for the 8950's or maybe a modification that can be done to allow the amplifier to use another type of tube?" After doing my research, and correct me if I am wrong, it seems the 8950 tubes use a 12VAC heater voltage instead of the normal 6VAC. Any and all help is greatly appreciated in advance.

Sincerely,
James, Owner/Operator
Eagle_Tronics

6KD6 is the same tube, with a 6 volt filament. You can wire two in
series and use them for replacements

Mike

These 'real simple' schematics aren't always the best thing to study. Quite often there are some shortcuts used, tricks being played, etc.

If you look at the circuit, the audio is being applied across the oscillator, Q1, after being amplified by Q2.

Any diode has a capacitance across it. Perhaps more interestingly, the capacitance changes depending on the voltage across it. This behavior is exploited in varactor diodes, but is true to a degree in all diodes, and even 'normal' diodes are sometimes used as part of a tuning circuit by exploiting this behavior.

A bipolar transistor can be thought of as 2 diodes, back to back, so twice as much capacitance.

In this circuit, the voltage being output by audio amplifier Q2 is applied across the oscillator transistor Q1. C5/L2 make up the tuned circuit which determines the frequency, but some of Q1's capacitance comes into play, too. Normally, it would be constant and ignored. But the voltage from the audio amplifier is causing the capacitance of Q1 to change, thus shifting the frequency by changing the capacitance in the tuned circuit.

This also is likely changing the amplitude, and I doubt the frequency modulation is especially linear. Thus, except for experimental purposes, this really isn't a useful frequency modulation circuit. (Amplitude modulation of an FM signal is considered a very bad thing for a variety of reasons.)

I would suggest starting by studying CW transmitters first. They are a lot simpler, and there are a number of commercial, or sort of commercial, rigs whose schematics are on line, often with very good descriptions of how the circuit works.

Try taking a peek at http://www.qsl.net/k8iqy/, http://www.redhotradio.com/ (go to Red Hot 20 information for the schematics), http://www.elecraft.com (download the K1 manual), http://www.fix.net/~jparker/norcal/smk1/smk1announce.htm (schematics are actually back on the Red Hot page), and probably best of all, http://engphys.mcmaster.ca/~elmer101/

Hope this helps,
didleydadidah

It seems that no one has mentioned any UJT (UniJunction Transistors) yet.
Also, I've noticed a lack of FETs (and MOSFETs). Do SCR/Triacs count as
transistors?

Dave

Did you take into account the increased acceleration due to the reduced mass of the rocket fuel as the flight progressed? Of course, with most small rockets, the mass of the fuel is probably almost insignificant compared to the rest of the vehicle weight, so the acceleration may not change much. However, another aspect of the acceleration is the rate at which the fuel is consumed, and this is related to the shape of the combustion chamber/solid fuel shape. Finally, while most small rockets don't go high enough to have air resistance change significantly, it can affect higher flying rockets.

I suppose it would be possible to mount a small accelerometer in a model rocket, and have the data downlinked via a UHF link. It might be interesting to downlink this and integrate it to determine rocket speed and altitude.

Dave

A reflection coefficient greater than 1??? When RC is equal to 1, ALL power
is reflected.
With a RC of 2.414, 5.8 times the power is reflected. Your transmission line
generates power.
You should patent it.

73,

Craig,

Consider if you will a piece of RG-58 or other small line at 1MHz. No need to go to audio as Reg might suggest (to get really large reactive components in Z0). Then put a reasonably high Q inductor with about +j50 reactance on that line as a load. Let's say it's 0.5+j50. The line characteristic impedance will be somewhat capacitive, let's say 50-j3...I think it's actually a bit more than tnat. Now...what's the reflection coefficient magnitude? When I calculate it, it's greater than unity.

I'd suggest that you NOT get hung up in assigning a physical significance to that. Someone once suggested to me that the formula for calculating reflection coefficient (given Z0 and Zload) is incorrect, but on careful, ahem, reflection, I decided it was just fine as it's normally given. Good idea to go back to a clear definition of reflection coefficient and not read anything into it that isn't given by the definition or justified by math relationships with other concepts.

Cheers,
Tom

> but I think I'd still aim someone towards a DMM.

No matter which way you choose to go, here are a couple of "cheap
tricks."

First, you can make a simple voltage-to-tone converter that makes it
very easy to peak or dip something with no need to look at a meter.
It's at least as responsive as an analog meter, and lets you keep your
vision focussed on a tuning wand or the like, instead of the meter. You
can use this instead of or in addition to a meter, or even add it to a
meter. In this case, it's most likely easier to add to an analog meter.

Second, you can build a simple circuit to give you high input impedance
for an analog meter...or even for a DMM. You can even put some gain
with it. An op amp non-inverting amplifier, battery powered, can work
with signals up to 10 volts easily, or even a bit beyond, without going
to a high voltage op amp, and that's enough for a lot of solid state
work. Put a resistor in series with the input and clamp diodes to
protect against connecting to higher voltages. With some care, you can
get to exceptionally tiny input currents and super high resistance, if
that's important to you. Back before DMMs were common, I longed for
more DC sensitivity in my analog meter, wanting to measure millivolts.
A gain-of-ten (or more) op amp circuit will let you see such small
signals. (Use a low offset, low drift amp, and/or provide an offset
null control.)

Cheers,
Tom

Hello Craig,

As you have found, your trial calculation gives an impossible result.
Perhaps the formulae you have used to calculate forward and reflected power
make the same assumptions as Smith and others adopted in order to generate
curves which could be usefully printed on a flat rather than on a useless
3-dimensional sheet of paper.

Hint 1: When calculating power from volts and current it is essential to
take into account their relative phases.

Hint 2: On REAL lines the current and voltage are not in phase with each
other because the characteristic impedance Zo is never a pure resistance.

As Ian, G3SEK, pointed out, one of Smith's convenient assumptions was that
Zo is always a pure resistance. It never is. Oliver Heaviside, of
ionospheric-layer fame, realised this way back in 1875 or thereabouts when
he solved fundamental problems relating to distortion of telegraph signals
along transmission lines and a little later distortion in telephone lines.
Data rates even in those days were of great importance. Those solutions,
ridiculed for years by Oxbridge PhD blockheads, are today equally applicable
to transmission of digital signals and TV waveforms.

It was American engineering mathematicians such as Carson and Armstrong who
took Heaviside's work into the 20th century and into radio. The Yanks, if
nothing else, are essentially practical !

Hi Reg,

OK, can we get down to brass tacks here? Are you suggesting that when I scale all impedances by Z0 that I can't read correct values from the chart, that they are inherently incorrect? Did you happen to quit drawing the grid lines right at a unit circle from the origin??

Specific example: scale to Z0 = 50-j10. Then, rho = 0+j1 results from a load of Z = 10+j50. The normalized impedance point that plots to is 0+j1, which seems right to me. For rho = sqrt(1/2)+j*sqrt(1/2), the load is +j2.414*Z0, which again is just what I expect from the chart...in fact quite in general, the chart simply plots for grid lines a field of Z(normalized) = (1+rho)/(1-rho), and you are not constrained to do that for |rho| <= 1 even though the printed charts typically stop the grid lines there, out of convenience. So I come down to the ultimate question: is it not true that Z = Z0 * (1+rho)/(1-rho)?

Note that the instructions for plotting normalized Z for rho = 0+j2.4142 say it will be -0.707+j0.707; so if my transmission line Z0 is 705-j705, then a load of 0+j997 ohms results in a reflection coefficient of 0+j2.4142. I _still_ don't have any problem with that... the bumble bee is still flying just fine, thank you.

863. Help on INTEC Mariner 2500 SSB and SEA 112

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-06 04:03:38 UTC
From: randy_radio@my-deja.com
Message-ID: <95nt2m$723$1@nnrp1.deja.com>
Source record: 54860

Hello. I have two marine radios here, one the INTEC that I am trying to get on HAM bands and the SEA 112 that came along for the ride. Neither unit will go into xmit when the PTT is pushed on the mike. The mikes PTT line on the INTEC terminates on a Molex connector. What pins on the Molex do I need to jumper together? Also is there a jumper on the antenna coupler jack needed to enable the xmiter? I do not have the antenna couplers for either unit. I also need the programming info for the INTEC. It uses a diode matrix for the synth. and it has 3!!! xtal ovens in it plus a Collins mechanical filter. I would like to get this radio on 80 and 40
meters.

Thank you,
Randy KB8ASO

p.s. Where would I get the EPROMS on the SEA programmed if I decided to do so?

> It seems that no one has mentioned any UJT (UniJunction Transistors) yet.
> Also, I've noticed a lack of FETs (and MOSFETs). Do SCR/Triacs count as
> transistors?
>
UJT's are useful for quick, one-off oscillators and certain kinds of timing
circuits. I don't normally deal with that sort of thing where I want a quick,
one-off kind of design for that sort of application. I have seldom messed with
SCR/Triacs also, but when they are applicable, they are a wonderful solution.

I am very fond of working with FETs. They are a different sort of challenge to
bias or optimize a circuit with. Note that I tend to work with low frequencies
(30MHz or less), so my choice of JFET tends to be optimized for that application.
Many of the higher frequency fets (e.g. 2n4416, 2n5486, j310) have good application
in low-medium frequency situations, but using them with conventional resistor
load, ac-coupled applications need to be carefully considered due to the biasing
issues. (It isn't really hard to use them, but the wide idss/vp spreads makes the
designer have to be aware of the issue.) Working with Fets is sometimes somewhat
like designing with Germanium transistors in low current circuitry, but requiring
even more care to get the ultimate or maximum performance.

Jfets can be very useful in super-low noise, but high speed, low distortion applications
where bipolars can give the designer some grief... Jfets do sometimes have more
noise than theory might imply though. Jfets also provide a linear resistor capability
that tends to be more theoretically interesting than practical (it can be used, but there
are serious
issues of device specification spreads.) Using the device in the ohmic region mode
is really wonderful when applicable. There are some tricks that can almost eliminate
the distortion (even better than the device alone.)

You might have to look to someone else regarding Mosfets, because my only
significant experience has been with the 3n128, the old dual gate things (e.g. 3n140)
and some of the other obsolete (RCA) fets with the substrate available as a low gm gate.

I don't mess with power RF, but I am sure that there are individuals who have good
suggestions for that technology.

John

> I'm looking to start building QRP transciever kits. I need to equip a
> bench for such work. <snip>

> A multimeter? Digital or analog? Features? Price?

Analog meters do a better job of measuring changing voltage/current.
Don't buy an expensive one, a cheap one is almost as accurate and
will probably last longer. My Altai HC-2020S (20K/V) cost 17 UKP
and has already given ten years of good service.

Multimeters are so cheap that you might consider buying a
digital one as well.

> A soldering station? Weller? WLC100 (40 watt adjustable) OK? Don't
> bother, just get a simple iron?

Soldering stations are nice but they are quite expensive. An 18W
Antex iron will suffice for most amateur work. If you intend to do
a lot of desoldering, you will probably need a 25W iron.

Once you have a multimeter, an iron and a roll of solder, you
can build a lot of useful test equipment.

A diode probe for measuring RF voltages.

A dip meter for checking the resonant frequency of tuned circuits.

An absortion wavemeter for checking for spurious signal from your HB TX.

SWR meter, noise bridge or impedance bridge and so on.................

73, Happy Homebrewing.

==========
SCRs are excellent to get a stabilised HV for RF valve amplifiers .
See QEX July-August 1999. page 50 and following.
Article by VE6AXW.
Example : 2400 V , 0 -1 ampere with 2400 V @ no load and 2397 V @ full
load
SRCs are used in primary winding of HV transformer .

No RFI reported.

Hi Matt -- well I don't know what ISS is. But to transmit just about anywhere -- you will need a license. For ham license -- see URL:
http://www.arrl.org/hamradio.html
To build your own transceiver can be fairly simple to very complex. For some ideas -- see URL:
http://ac6v.com/homebrew.htm
There you will find some moderately simple projects as well as two good books on "Build Your Own Intelligent Amateur Radio Transceiver" and "Radio Receiver Projects You Can Build." Going thru the HomeBrew projects will find a transmitter as well -- but you must be licensed.
You may want to consider a kit -- see URL:
http://ac6v.com/kits.htm
I have built projects in the past and although time consuming it is rewarding. Todays technology makes it difficult to build anything approaching a modern transceiver.

Read the reviews on "Build Your Own Intelligent Amateur Radio Transceiver" at Amazon. com

UJTs make extremely simple oscillators, although the output waveform is more of a sawtooth than a sine wave. You can use them to build blinking lights, using only four components (UJT, resistor, capacitor, LED).

They seem to be the forgotten transistor, at least, judging by their availability. They're almost as hard to find as germanium transistors.

Dave

P.S. Standard Disclaimer: I work for them, but I don't speak for them.

Any idea what the meter does with 1, 6, 7, and/or 9?

883. Overvoltage SCR triggering problems

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-07 21:44:29 UTC
From: lagagnon@fakesprint.ca
Message-ID: <3a81b9a5.1524289@news.sprint.ca>
Source record: 54879

I have a homebrew 13V, 20A power supply I am just finisishing testing. Most of the time it works just fine. However, on three occasions it has blown its 25amp fuse which sits between the overvoltage thyristor (SCR) and the filter capacitors. I believe the thyristor is triggering. The overvoltage circuit is the same as that found in "The Art of Electronics": a 15.1v zener diode going to ground through a 0.1uF cap and a 100 ohm resistor, the zener triggering a 30 amp thryristor. The occasions when the fuse has blown have been 1) rapid increase in drawing 5 then 20 amps 2) when I had a bad connection to a circuit drawing 2 amps and it sparked at the terminals. This suggests to me that a voltage transient of some sort might be triggering the zener to over 15.7 volts thereby in turn triggering the gate of the SCR.

The regulator and other circuits appear to be working very well and there are no intermittent shorts elesewhere in the supply. I hesitate to test that it definetely is the overvoltage circuit by disconnecting it temporarily to see if the problem disappears. Any suggestions out there on how do deal with this problem??

Message-ID: <95sgmj$8h5$1@nnrp1.deja.com>
Source record: 54882

Hi Barry!

I didn't know it at the time, but I had made Q-dope already!

I was attempting to manufacture napalm, and I needed a gelling agent that would retain the molecule soup called gasoline. I remembered reading smtg about palm oil, but as soon as I discovered that polyester foam would dissolve in gas, I knew I had a recipe.

I would have had more fun if I also had time to synthesize a low velocity propellant that would ensure both ignition and inertial droplet dispersion. Unluckily I was in Physics school back then, and we couldn't mess up too much with chemicals...

Last night a good friend of mine told me she can provide me with a some high grade ammonium nitrate.

Oh, only 20 years too late!

- Don't worry, I ONLY worked on experimental scale devices, never more than a few ounces at a time, and with no illwill twd anyone...

From: Ralph Mowery <rmowery@dialpoint.net>
Message-ID: <3A81C7FC.DFDF332C@dialpoint.net>
Source record: 54881

It is doubtful that you could use the same relays for anything much above 30 mhz. The segments in them are probably nowhere neat 50 ohms and are long in terms of wavelength. That means that you have inserted a piece of transmission line that is somewhat lossey but more important is that the impedance bump in the line. To do the switching at those frequencies you need some kind of coax realy rated for the frequencies that you are using.

Ian, I used to share this belief, but I now have my doubts. A microwave oven works at one well defined frequency. Isn't that a f. that is easily absorbed by water?

And, isn't deionized water also a pretty decent electrical insulator? (I even saw it used in hydraulic remote control of high voltage switches!). Yet, pure water does heat a lot in a microwave....

I find this confusing enuf not to trust the method. I'd rather try this diathermic treatment at HF before deciding if a dielectric is low loss at that frequency.

What do you think?

a different suggestion. Seems you are in a group of two of my friends
who use SMD, the other is LA7MI, I still like to drill holes in pcb

Suppose 2N7002 is similar to my favourite 2N7006 - particularly
popular here since I got 2500 items for free, somebody may say VN2222
or VN2408 - provided you know the use

could write a list of which transistors used here, but it has little
or no interest for anybody else, 2-300 different types, based on the
availability and sources/friends who persuade me to help them to get
rid of some components. When I got 3000 of BC238B, I really do not
care whether you call it 2N2222, 2N4401 or 2N3904
In Europe we use the term TUN (transistor universal NPN), while you
tend to say 2N2222
and still in order of communication, when accurate data is not
important, we may call it 2N2222 on this newsgroup, BC547 on another

The only but important problem remains, how to be aware of the
available ressource. One suggestion is to mark the PNP devices with
BLUE paint, and the NPN with RED, and forget the specifications -
except for very very special purposes and VHF/UHF/SHF.

889. Re: Smith Chart Programs

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-07 23:03:20 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A81D438.C3742C9@eznec.com>
Source record: 54886

The Smith chart is easily extended to include values of reflection coefficient greater than one. This is often used for amplifier stability analysis and oscillator design. For examples, see Fig 6.2 in Vendelin, Pavio, and Rohde, _Microwave Circuit Design Using Linear and Nonlinear Techniques_ (Wiley, 1990), Fig. 2-27 in Rhea, _Oscillator Design and Computer Simulation_ (Noble, 1995), or Figs. 2.2.4 and 2.2.5 in Gonzalez, _Microwave Transistor Amplifiers_ (Prentice Hall, 1984).

The limitation of real characteristic impedances would be a severe handicap in the MF and below world where Reg apparently spent most of his career. But with decent quality cable at HF and above, the error introduced by the limitation is typically much smaller than your ability to discern it. And 50 ohms resistive is so widely used for network design that the limitation is no handicap at all in the vast majority of circuit applications. The Smith chart continues to be a wonderfully intuitive tool for many design problems. If accuracy beyond a couple of significant digits is necessary, the engineer should think carefully about the reproducibility of the design using real world components in a real environment. And in that case, computer analysis of not only the design itself but of the effect of component and environment variations is called for.

Roy Lewallen, W7EL

Let me emphasize some things that Rod said...

You can build a transceiver to be as simple or as complex as you desire. A perfectly useable transceiver can be designed and built in a weekend, or it can take many years. You can spend $20 in parts, or you can spend $2000 in parts. These are all design decisions that you make.

Rod also pointed out that you need a license to transmit on any frequency. What he didn't clarify is that you need a radio amateur license to transmit in the U.S. using a radio that you built. There are no other license categories that can operate equipment they build. There are certain categories of transmission that can be engaged in without a license, but they all require that you use equipment which has been type-accepted by the FCC.

That being said, since getting an FCC license, while a worthwhile goal, might not fit in your semester (although to an EE student it shouldn't be real tough), Michigan has plenty of amateurs, and I don't think it would be all that tough to come up with someone who would help you with the project, then operate it on your behalf. (Unfortunately, I'm a couple hours from Oakland so I can't be of a lot of help here).

I have personally designed and built the weekend special sort of radio, so I know it's perfectly possible. I have also built, but not designed, the 6 month flavor. Not far from you, up in Fenton, is one of the best radio designers on the planet. I don't offhand know of anyone in your neighborhood, but it shouldn't be too tough to find someone.

We used SCR's as Power Amps in the transmitters we used to send messages
to submarines here at the Navy ELF transmitter site. We used them to
convert DC back to AC at around 60Hz frequencies and then out the
antenna. Unfortunately, we don't have a ham band at 60 Hz!

At least some of the older ARRL handbooks have articles. Though a bit
disjoint, my 1973 copy has one. If you cannot locate, I could scan
the slightly yellow pages send (3-4 pages). I built one, but it was
before I was documenting my projects so well. Expect was based on the
aforementioned article.

899. New PSK Software

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-08 02:01:46 UTC
From: Dave deSouza <g3vfp@btinternet.com>
Message-ID: <95surq$h1f$1@uranium.btinternet.com>
Source record: 54896

Hello all.

Just to say I have added PAL-PSK software to the files on my download page. It is relatively new psk software from Erik VK7AAB. It has waterfall, and scope display. Can be used with upto three channels, and has a logging report utility built in. Developed using Visual Basic, with the PSK Core taken from Moe AE4JY's excellent work. Easy to set up, it is worth taking a look at. This version was completed on Dec 18th 2000.

Have a play with it, and see what you think.

http://www.btinternet.com/~g3vfp/download.html

Regards,

Dave G3VFP.

> kV/cm w/o breaking down!

Comparing the HT110 product to water, since they have
similar boiling points, shows some interesting comparisons.

Water has about 2/3 the viscosity meaning it is easier to
pump.

Water has about 4 times the heat capacity, meaning that for
equal masses heated an equal number of degrees, the water
will absorb 4 times the heat.

Water has about 10 times the the thermal conductivity giving
better heat transfer.

And most significantly, water has about 36 times greater
latent heat of vaporization.

So for purely liquid cooling, water is the better performer,
and for vaporization cooling, water is the far superior
performer.

This stuff might be fine for a CRAY and its modest cooling
requirements, but for a several hundred kilowatt
transmitter, it is not likely to replace water any time
soon.

They rated the breakdown voltage as 40 KV/inch.

I wasn't going to say anything, but two of my favorites
haven't been mentioned. They are both on the edge
of obsolescence (but then, isn't everything?).

For small signal RF, I have long used the 2N5179.

For medium power RF (like strong RF or IF amplifier
stages), the 2N5109 (or the NEC 2SC1252).

But remember, I'm a retired "old fa**".

> water?

I am not sure how many times this needs to be said...

Microwave ovens operate at different frequencies in
different countries.

Microwave ovens do not operate at any resonant frequency of
water molecules.

Water is a broadband absorber (lossy dielectric) at an
extremely broad range of frequencies.

> And, isn't deionized water also a pretty decent electrical
> insulator? (I even saw it used in hydraulic remote
> control of high voltage switches!). Yet, pure water does
> heat a lot in a microwave....

The heating has nothing to do with actual elecrical
conduction. What you are seeing is hindered rotation of the
water molecule as its dipole tries to align with the applied
electric field. The rotation requires energy and it is this
energy converted into heat.

Adding a small amount salt to distilled water causes a huge
increase in its DC conductivity, but it only increases the
microwave losses slightly.

Don't feel bad, there is almost always a need for custom, non IC solutions. The parts that you noted are RF parts, and I don't think that other such suggestions were made. Those do appear to be good choices for miscellaneous RF applications. The 2n5179 works at frequencies higher than the 2n3904 type parts. You have suggested some parts that carry father through VHF into low UHF.

Good suggestions, especially for a Ham radio group!!! Don't feel bad about being an old fart, because I am one also!!!

Analog Devices, for sure, and I think Burr-Brown (TI/Burr-Brown), have some voltage-controlled amplifiers. The AD ones I'm thinking of have a low noise amp preceeded by a resistive ladder network with the "tap" driven by the control voltage. The result is control very nearly linear in dB, and good overload performance in that lower gain results in higher input intercept point. The noise, as I recall, is pretty respectable, though not necessarily state-of-the-art.

Cheers,
Tom

(I'd also consider just using a good wide dynamic range op amp...but I'm kinda interested in just enough gain to get into a good ADC...)

There are probably very short pulses when the circonstances you mention occur.

First of all, try to identify the pulses, SCR disconnected, with a storage scope. Maybe the solution is a kind of very light RF filtering: a little capacitor across the SCR or something similar. Be sure you kill the pulse itself. Don't act just on the trigger of the SCR.

Good luck !

Larry Gagnon <lagagnon@fakesprint.ca> a &#65533;crit dans le message : 3a81b9a5.1524289@news.sprint.ca...
I have a homebrew 13V, 20A power supply I am just finisishing testing. Most of the time it works just fine. However, on three occasions it has blown its 25amp fuse which sits between the overvoltage thyristor (SCR) and the filter capacitors. I believe the thyristor is triggering. The overvoltage circuit is the same as that found in "The Art of Electronics": a 15.1v zener diode going to ground through a 0.1uF cap and a 100 ohm resistor, the zener triggering a 30 amp thryristor. The occasions when the fuse has blown have been 1) rapid increase in drawing 5 then 20 amps 2) when I had a bad connection to a circuit drawing 2 amps and it sparked at the terminals. This suggests to me that a voltage transient of some sort might be triggering the zener to over 15.7 volts thereby in turn triggering the gate of the SCR.

The regulator and other circuits appear to be working very well and there are no intermittent shorts elesewhere in the supply. I hesitate to test that it definetely is the overvoltage circuit by disconnecting it temporarily to see if the problem disappears. Any suggestions out there on how do deal with this problem??

I wonder if the regulators loop response is under damped.
In that case in response to a load increase the output voltage would initially decrease and then the regulator feed back loop would cause it to rise back toward the desired voltage, but because of delay in the feed back loop the voltage would over shoot the desired voltage and then drop back to the desired voltage.

This can be observed with a storage oscilloscope on the supply output and switching on and off the maximum load.
You may be able to observe it on a conventional oscilloscope if the transient is slow enough.

This is a standard test that I run on new power supplies that I am going to use to power radio equipment. 12 V supplies that were designed for applications that had a relatively constant load will some times have a terrible transient response to a load change of 0 to 100% which a transmitter effectively produces every time it is keyed. Some times it is necessary to place a preload on the power supply to help tame this type of problem.

You can explore the SCR triggering problem by placing a medium value resistor (100 ohms) in series with the anode lead. In this way when the SCR is triggered it will not blow the fuse or stress the components but will allow you to see if the SCR is being triggered.
A LED with a 1K series resistor placed in parallel will give you a visual indication of the SCR being fired.

I agree entirely with Brian. The eventual under damping is then a design problem of the power supply. The preload can help, but if the transient voltage response is not satisfactory after you put a reasonable preload (up to 1/10 of the maximum load), you need to optimize the feed back loop. It's not very easy. When you attempt to modify the values of the feed back loop (resistors and capacitors) there is a risk of oscillations.
You can use a power switching transistor and a low frequency square wave generator to switch on and off a resistive load at a convenient rythm and speed up the set up process.
That's the way I use to optimize other feedback loops like PLL: I slightly alter the division ratio at a very low frequency and I observe the shape of the system response.

I understand that you might want to build one, just for the sake
of building. However, there are a lot of phone patches that come
up for sale in rec.radio.swap, on E-Bay, and at all the local
ham fests. They usually are going for only $15. You can save
yourself a lot of work and headaches finding parts by just
picking up a used one.

The most common ones are the old Heathkit HD-19 and HD-15
phone patches. You might want to get the schematics of these
uints to get an idea of what you are building. They are pretty
simple. The schematics for these are available at

http://members.accessus.net/~dwentz/kb9jja/heathkit/

for the HD-15

http://www.circuitarchive.co.uk/heath.htm

for the HD-15 & HD-19

For low frequency lines, it's possible to modify the line in
such a way as to make Z0 a real number by making R/L=G/C. This
makes Z0 equal to the square root of L/C. Heaviside and Preece
argued this all out in the 19th century in relation to distortion
in telephone lines. This is elementary and I'm surprised none of
the controversialists on this newsgroup has bothered to mention it.

Indeed, I worked in a plastics shop where the old shop sink had running water in one faucet, and runnig acetone (or sometimes MEK) in the other! This was 30-35 years ago and I don't percieve any ill effects.

>thryristor.
I note in Astron and others, a .1 or so is from the gate to the
cathode (probably in a bypass function) and a 4.7uf to 10uf is usually
across the resistor to filter out narrow pulses and in some a second
100 ohm is from the resistor/capacitor/zener junction to the gate.

I love the case, and the front panel gives it a nice Buck Rogers look.

One thing I miss about the old tube radios is the ornate cases that made them look like a piece of furniture or something that at least belonged in prominant view.

Still at my folks house, in the basement (for the last 20 years), is a Sears 5-band radio with cats eye tuner and a 78 turntable which uses steel needles. The thing is huge standing about waist high. It also has a 12 inch electromagnetic speaker. Lovely item.

Hmmm...I think you've quoted that out of context. I think Roy's comment was firmly in the context of Smith charts: _IF_ they are limited to handling (being normalized to) real Z0 only, that would be a handicap in the in a world where lines commonly have a complex Z0. I quite frankly have a lot of respect for someone who spent a lot of time working on lines where the simplification of assuming real Z0 was inappropriate, in an era before ready availability of calculators with hyperbolic functions, and personal computers with scientific spreadsheet programs and the like.

(Of course, as I've said, I don't believe that Smith charts _are_ limited to real-valued normalizations, nor to |rho|<=1. And I also don't believe that one always has the option to use lines that have real-valued Z0 at all frequencies of interest. A Smith chart displayed on a computer screen, where the computer takes care of rapid, accurate calculations, lets me easily use the visualizations I find so helpful while removing the tedium of part value calculations,normalization and plotting, and making it easy to read all sorts of different values to whatever precision is appropriate.)

Cheers,
Tom

Perhaps things have changed, but the chart I just looked at says the spectrum below 9kHz is unassigned. AFAIK, we are free to use it as hams. I suppose we might get someone's attention if we started to put significant power out at, say, 1kHz.

926. TM-V7 WIRELESS REMOTE PROJECT STATUS

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-08 20:20:08 UTC
From: "F.A.C.T." <atomski@EUnet.yu>
Message-ID: <3A82FF78.77B55ADC@EUnet.yu>
Source record: 54825
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment,rec.radio.amateur,rec.radio.amateur.digital.misc

INTRODUCTION

Hello again,
my name is Vladimir and my HAM callsign is YZ7REA.
This is my second addressing to the general HAM population worldwide
in regards to this project. For those of you that are familiar with
the project goal I can say that I'm not gonna bore you too much. But
on the other hand I'll give a "short" brief about this project for those
that don't know whatta heck I'm talking about.
"TM-V7 WIRELESS REMOTE"... Sounds interesting? Well it sure is!
And it's simple too! For all of you that are familiar with this KENWOOD
mobile radio and own/would like to own one, this project will open a
whole new view. The goal of this project is to separate the detachable
front panel from the radio and establish the digital communication
between them at distances of several miles or even more. Why? For many
reasons. If you live in a heavily populated area and have problems with
TVI, live in an area where the density of HAMs is big or you just wanna
be "on a top of a hill" and be able to make contacts at larger distances
without using a lot of power or spending a lot of money on directional
antennas, rotators and tracking/positioning systems this project will
give you all that you need.

DISCLAIMER

Before I go further with explaining how the system will work
I have to say that this project will NOT be in compliance with laws in
some states or countries. Respect that as you respect the HAM code that
prevents you from transmitting outside the boundaries of amateur bands.
First of all let me tell you that I won't be selling this system to
anyone nor will I sell schematic diagrams or any PCB's etc. This is my
idea and I want to share it with HAMs worldwide. So, what you choose to
do with it is your own business. All I ask of you is that you mention
my name and callsign if and when you post any info about this project
on/in discussion forums, publications magazines etc. Second, if any of
you should choose to use my idea for commercial purposes I ask that
you write me an e-mail notifying me about that. Third and the last,
I'm not going to responsible if any of you choose to use this system
even if it means breaking the law in their country/state.

TECHNICAL STUFF

I'm working on the system whenever I have spare time on my
hands (and that ain't often). So, I'll keep you informed as the project
develops.

1. General info

According to the KENWOOD TM-V7 service manual the four pins that you
can see when you remove the front panel (LCD/control unit) are:

-----
[o] pin 4 - 9.6V
[o] pin 3 - GND
[o] pin 2 - Data out
[o] pin 1 - Data in

After measurement with an oscilloscope and volt meter I found this
data to be TRUE. What you should know is that data communication is
asynchronous with speed of 3125 bps (3K2). The control unit checks
to see if the panel is connected to the radio every 0.5 seconds and
if it misses two counts it assumes the panel is taken off and shuts
off the radio. So, this means that you need a FULL-DUPLEX link to
be able to connect these two together. The easiest (I'm not saying
the best) way is to use pair of full-duplex radios on 900MHz, 23cm,
13cm or any other band that has a "amateur digital communications"
slice of the spectrum in it. Of course you have to be sure to use
the band that is legal for this stuff e.g.: packet radio link freq.
I'm using a 3cm ATV FM transmitter with 5 sub carriers on each side
and no video "carrier". You can use any carrier from 5-8.28 MHz.
You'll need to relay the following signals from the CONTROL PANEL
to the radio:

1. PTT, UP and DOWN button control*
2. MICROPHONE
3. PANEL DATA OUT (3125 bps)
4. DATA TERMINAL TX
(connection from PC, packet modem, SB etc. max. 9K6)
5. AUX (used for remote switching of PA's etc.)

You'll need to receive the following signals from the radio:

1. VHF RX AUDIO
2. UHF RX AUDIO
3. PANEL DATA IN (3125 bps)
4. DATA TERMINAL RX
(connection to PC, packet modem, SB etc. max. 9K6)
5. AUX (used for remote switching indication etc.)

* Three button control via a single wire/carrier can be achieved by
using the 3 different tones. Something like CTCSS, but they can be any
frequency even hearable from couple of hundred Hz up to couple of KHz.
By using a PLL DETECTOR on the other side you can precisely determine
which button/key has been pressed.

2. Transmitter(s)

You can use many solutions from cross-band (example 23/13cm)
to in-band full-duplex radios. I leave this to you to decide. As I said

I will be using 3cm amateur microwave radios, both for PANEL and RADIO side of the link. Small antennas, little power, huge gain, simplicity of construction, great directivity and the most important thing good frequency separation in free space at antennas just couple of feet apart are why I decided to use this band for my project. As little as 10mW and a 36" dish will cover the distance of more than 15 miles if line-of-site is present.

3. Receiver(s)

Commercial LNB's, SAT dishes and SAT receivers with small mods can be used.

4. MODULATORS/DEMODULATORS

This really depends on the type of radio that you're planning to use, but bear this in mind. All the signals you need to relay are in fact NBFM signals. This means that you DON't have to use WBFM sound carriers like I did. There are certainly much better solutions than mine but this one, as I said before, was the easiest one for me since I already had some equipment that I wasn't using.

5. COSTS

This is also very relative, but if you use some old uW equipment for 3cm like I did it comes very cheap to have such a system. All taken in consideration the total cost for this system shouldn't exceed $150.

5. LIMITATIONS

Laws that prohibit this type of data transfer, line-of-site is a must, very bad weather like heavy rain, snow thick fog etc. can downgrade the system reliability. More than one TM-V7 WIRELESS REMOTE system at the same frequency in each other signal path can probably interfere with each other (I haven't tried this). And probably more...

6. BENEFITS

Just think about it for a sec!

Well I'll rap it up for now. Feel free to ask any questions regarding the system, but please don't ask for any schematics 'couse I still haven't drawn them yet. They're all in my head for now. I'll probably put more info on my web page later on once my system is up and running and monitored for some time.

****
I'd like to thank KENWOOD for "helping" me with this project and directing me to the nearest KENWOOD dealer to spend $40 for the Service Manual. Also thanks to KENWOOD technical support who told me that if they gave me the DFK-3C for this project they'd go bankrupt. :) I know that they get all kinds of weird requests every day, but I also know that every Tom, Dick and Harry don't make something like this and share it with fellow HAMs all around the globe.

****

As for me... No medals please! :) I'm proud to be a HAM!

Your HAM friend from YU-land
YZ7REA Vladimir

I have to plead ignorance in not having read Heaviside's and Preece's 19th century works, nor ever having had to design telephone transmission systems. Is this modification commonly done, and why? And briefly, how is the line constructed or modified to make this happen? You're pretty well stuck with R for a given conductor size, so it appears you'd have to intentionally increase shunt loss G and/or make the nominal high-frequency impedance (sqrt(L/C)) extraordinarily high. You can't get a very high L/C ratio in practice with reasonable conductor spacing, so my guess is that you'd end up having to intentionally increase G. Or is it just done by periodically inserting lumped inductors? But this is pure speculation on my part -- it's not clear to me why you'd necessarily want or need a purely real Z0 in the first place. Why is it done?

It's possible that it hasn't been mentioned because of the general lack of experience of the posters (some of us at least) in dealing with low frequency lines. I had thought Reg had, but I seem to have been mistaken on that account.

Incidentally, my motive for mentioning it was an attempt to understand why Reg feels that not being able to easily normalize a Smith chart to a complex impedance is such a handicap, while the multitudes of daily users of the charts aren't bothered. Since I was wrong about his MF and below experience, I'm again at a loss to explain it.

Reg was going on about the Smith Chart assuming a real Z0, when
in fact, as Tom Bruhns pointed out, the assumption isn't necessary.
Evidently, in the early days of telephony, the distance one could
transmit a signal was limited by the dispersiveness of the line.
Heaviside realized that, given the condition that R/L = G/C,
the phase velocity of a given line would be the reciprocal of
the square root of LC. This is a constant which would, theoretically,
produce a distortionless line. Heaviside advocated the use of
lumped inductors spaced along the line to provide the needed inductance.
British electrical engineers of the time didn't think much of this idea,
so it was left to an American, George A. Campbell, working for The
American Bell Company to design the first practical coil.
I don't know whether or not anyone cares about low frequency
transmission
lines any more. I posted what I did to gently remind Reg that the
assumption that all transmission lines have a large reactive component
at
low frequencies is not always valid.

You need to load the amplifier sufficiently so that it's not getting overdriven by the source. That said, if you load it too heavily (too little capacitance on the loading capacitor) you will get lower efficiency.

So it's a tradeoff between efficiency and power handling. That's why the newer rigs putting out 200 Watts instead of the old standard 100 Watts have become so popular. You can hit the amplifier hard, load it heavily, and get plenty of output.

But it's always wise, as you do, to make sure you are still getting more output when you are driving harder. Try driving with a CW signal, a series of dots from a keyer, while adjusting for maximum output power. It the peak output is close to the legal limit and the current isn't too high, you can stop there.

1. Adjust the drive to the point where the output stops increasing.
2. Adjust loading (and then tuning) to get more output.
3. Increase the drive again.
4. Repeat steps 1, 2, and 3, with step 1 or 2 as the last one.
5. Verify that you are not exceeding legal output power. If you are, back down the drive.
6. If you can't get the power you think you should, perhaps your exciter needs more output or the amplifier power supply needs checking.

Elaborating a bit on what Bob wrote: Too lightly loaded and too much drive and you'll get flat-topping in a linear amp, though for CW you might not notice the difference...but you're wasting the tube's capability. Too heavily loaded and the tube can't conduct hard enough to pull the instantaneous plate voltage very low and efficiency suffers. Heavily loaded means you've reflected a low load resistance to the plate circuit, and the load line is asking for a lot of current, possibly more than the tube can deliver. Lightly loaded means you've reflected a high load resistance to the plate circuit, and the tube never conducts as much current as it could be conducting. "Optimum" is generally somewhere between those extremes. But optimum also involves tube life and distortion.

As for the efficiency you're seeing: I'd say it's not too bad for AB. I recall that the FCC used to give me a slightly disbelieving look when I said that our broadcast transmitter was running right around 80%...the were calibrated to 75% for class C. Theoretical max for class B is pi/4, I believe, but that assumes the tube will conduct at zero plate voltage, which of course it won't. And AB is marginally less efficient than B, the degree depending on the bias.

Cheers,
Tom

Barry,

Thank you for all the comparisons!
I guessed it would be thermally inferior, but not to thi extent.

I think the only real advantage of this stuff lies in that you can
bathe solid state electronics in it.

It may be good for low power tubes, but I have no idea if it has ever
been tried.

Do you know if high power transmitter cooling systems include water
conditioning, or at least monitoring? Also, more to the point, do you
know if they're designed to require water to retain a degree of
electrical insulation?

JW,

As for Cray, I think the co. went under or got bought out a while ago.

If you search for "Cray supercomputer display" you may find something -
I remember reading of a co. that kept one for show. Yet I'd be
surprised if none at all were in use.

I think they do have display value. They had a radial layout aimed at
keeping wiring short that gave them a sci-fi look. Some had windows and
lights on their sides, and you supposedly could see the coolant bubble
away.

Johnny,

I think there is a chance component in dealing with those substances.

Usually, the direct short/medium term toxic effects do show up rather predictably, and you're out of danger by now.

On the other hand, the cancer risk is a bit different, i.e. being exposed to them is like casting dice. There is a probability that something will go wrong and that a molecule will alter the DNA in a cell so that it starts multiplying.

Nobody know exactly how that happens, although the statistical evidence is by now rather good for many substances and many related types of tumors.

Some tumors develop quite quickly after exposure, others have long latency periods.

I'm sure Dr. Ornitz will concur, at least in part. I guess the risk of contracting tumors decreases as time goes by uneventfully after exposure, but I don't know much about that.

In my case, I had repeated exposure to gasoline (at one point I found myself with my mouth and face full of it due to a bizarre syphoning effect in a motorbike's tank!), chlorinated solvents, and formaldehide.

That was over 20 yrs ago. I've been tested for four types of cancer on four different occasions, but I've been lucky so far.

Hank,
By the time you've replaced all the switches, you'll be well over the
$50 minimum order level.... But I don't think that Racal have any in
stock anyway. Seriously though, there is a very near equivalent in the
Jameco Catalog that I *have* used, about 30 cents each, from memory.
Buttons are a bit loose but can be fixed with a drop of hot melt glue.
One tip, it is in some cases much easier to replace just the elastomeric
membrane inside the switch, than to desolder the switch itself,
especially those under the ICs, as you will see when you look at the
front panel. I have not tried this with the Jameco switches, only with
the originals. If you do have any good ones you can do this trick with
the inaccessible ones. Also if any of the switches have gone, then
they will likely all go soon, unless they have been replaced previously.

Great counter though!

South Normanton & District Amateur Radio Club,
in association with the G-QRP Club, are holding what
promises to be the year's main amateur radio event
in this area.
"Junction 28 QRP Convention", will be held on Saturday
17th March 2001, at the Village Hall Community Centre.
Market Street, South Normanton, near Alfreton in Derbyshire.
Located just 5 minutes from Junction 28 of the M1 motorway
and the A38, this will be a traditional radio event, organised
in the true spirit of amateur radio.
All under cover, there will be a good variety of stallholders
with components, kits, vintage and radio surplus, plus the
G-QRP Club stand, club stands and special interest groups.
There is a programme of lectures by Rev.george Dobbs G3RJV,
Rob Mannion G3XFD (Editor of Practical Wireless), Tex Swann
G1TEX (Also from Practical Wireless) and Douglas Pitt of the
Narrow Bandwidth TV Association (NBTVA) who will giving a talk
and live demonstration of mechanical television.
Hot and cold food and drinks will be available, plus a licensed bar.
Talk-in will be provided by GB0LOW on S22.
Doors open 10.00am.Admission is just ?1.00. FREE PRIZE DRAW.
Further details from the organiser on 01623 465443.
We look forward to seeing you there!

Hi,

I am in need of a few pointers to information on the effects of propagation changes on the short term accuracy of time and frequency signals at LF and VLF. Some months ago there was a mention here of a list or newsgroups where this had been kicked around but unfortunately I didn't bookmark it at the time.

Any info as to likely sites would be much appreciated. I have, of course, got the search engines churning here myself but any extra input would be very helpful.

TIA de Joe, G3LLV

Source record: 54747
Cross-posted to: rec.radio.swap,rec.radio.amateur.homebrew,sci.electronics.equipment

I have for sale a Systron Donner counter model 6244A, compact size (approx 9"W x 3" H x 15" D) covers DC to 4 GHz (tested to over 5.5 GHz) and is one of their phase-locking counters. When you input a signal the counter acquires it a d displays it in less than a second!

Counter has a built-in 10 MHz high-stability oven stabilized reference oscillator, is in extremely clean cosmetic condition and works on all ranges just as it should.

I want $175.00 obo for the counter plus shipping from 92870

Thanks

John

these TOKO switches are weird..
all are stuck!!
i removed one and took it apart and for the life of me i can't tell how or why it used to work..
there are only 4 parts to the one i disassebled..
1. pushbutton, it just pulls off
2. the plunger, you can wiggle it out..
3. inside the plunger there's a black sort of piston..
4. and last the switch body with the contacts which are part of the solder pins for mounting..

i don't know if someone took this apart before and lost some pieces..
i have a good counter but i'm not about to experiment with it till i find replacements..
it's a neat counter..
sooner or later, i hope i will find a source for TOKO momentary pushbutton switches or a close substitution.
so far the TOKO site hasn't been of any help, i gues maybe i'll call them monday..
mouser and digi-key have nothing..
i can't access the MCM electronics site..
i'll try Jameco next..
thanks

ICOM IC-O2AT handheld in excellent condition. Late SN..Comes with a drop in type battery but no drop in charger. Battery is rechargeable with a cigarette lighter plug in cable which also operates the radio.The radio also includes all of my original shop and factory info on the O2AT series as well as a manual. The receiver has been opened up to receive the WX channels. My experience with ICOM covered 17 years in Dallas.

I once saw something like this on eBay but never since. Here is what I want to do (Build or buy). This device has an audio input, and a mic output (like a 4 or 5 pin) to go to another radio as a transmitter. So, what it does is this: Audio coming in through the audio input keys the mic circut and send the audio through it. So, I'd have the audio input coming from my scanner and the mic output connected to my Kenwood Mobile radio. When sound came from the scanner, it would transmit this sound over the mobile radio. I hope this makes sense. Anyway, what is this device called and is it easy to build? Or, where can I buy such a beast?

Thanks,
Matt

I'm finishing a course (as a substitute-teacher) at a "Technical College"
(used to be called a "Vo-Tech School" for a teacher who is dying, and in
my classroom are some twenty or so Motorola mobile radios T81XTA7DA3BK
and a few of what look like "base" units (but I didn't think to look for
a model number) given to the school by the Kansas Dept. of Transportation
(or maybe the Highway Patrol) when it moved to an 800-MHz trunking system.

The school has absolutely no use for them (it does not teach any course
even remotely related to radios or radio repair), and the xcvrs are just
occupying much-needed space.

Does ANYONE have a use for these things?

They pretty much leave the monitoring up to the operator.
Then again I worked on the little 200 KW ones as well as induction heating
and ISM units.

> Also, more to the point, do you
> know if they're designed to require water to retain a degree of

Sho nuff. We used distilled, or deionized water.
Wreaks havoc with brass fittings.
Most tubes have a "getter" installed at the inlet to keep the corosion down.

Commercial water-cooled transmitting tubes use distilled and deionized water. It is normal to include continuous conductivity measurement devices to monitor the water for a buildup of conductive contaminants.

Vapor cooled (evaporative) tubes also need distilled and deionized water. In addition to the problem of conductivity, any buildup of contaminants will reduce the heat transfer of the tube's anode.

A good discussion of this may be found in the Eimac book, "The Care and Feeding of Power Grid Tubes."

Right - I remember a nuclear reactor engineer who worked with heat exchangers containing molten sodium on one side and pure, clean water on the other. He said all the problems were with the nasty aggressive substance that corroded everything it touched... namely, water.

Clapp oscillator seems to be disregarded over 40 years ago, and little information is shown in amateur handbooks, often amateur style authors seems to think it is bad, so no need to discuss it, but for some applications it may still be worth considering.

Need some info on capacitor relations for the Clapp-oscillator. I am well aware of problems with varying output, but tuned frequency range is small, and the 2.2MHz signal is fed to CMOS divider for 136-138kHz output

May use BF199 in the VFO, with 10nf between emitter-basis and 3n3 to ground, 300pf tank capacitor and 20 H coil. Could the tank capacitance be larger? Copyed a circuit designed by OZ6NF in 1963, for 4.2-4.4MHz, but he used AF124 (=2N1744), is actual yfe substantially higher for germanium transistors than silicon?

Matt,
I think you are looking for is sometimes called a "mobile extender". This is a vox circuit which just keys up when a voice is heard in one radio. One was described (and then updated) in 73 Amateur Radio Today, November 1993. This was a 2 way circuit... sounds like you would need just 1/2 of it. Easy to build. If you can't find the article drop me a note.

If the SCR gate is monitoring the regulated output.
I had a similar problem with a low current supply. It appears that
when the load current changed rapidly the regulator overcompensated
and the output voltage went high long enough to trigger the SCR.
Placing a 100 uF cap at the output fixed the problem. The output
current of my supply was only 0.5 A.

The Clapp oscillator has been superceeded by the Vackar oscillator, which is generally
considered to be the ultimate VFO technology. Unfortunately, it is not well documented
in the literature. I think it was in Ham Radio once. I have never been able to get a copy
of Vackar's original paper. Since you are in Europe, you may have a better chance of
getting a copy of the Vackar paper, which was in something like the Proceedings of the Tesla
Institute.

979. General Radio 1603A impedance bridge info?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-10 20:17:48 UTC
From: Nick Kennedy <nkennedy@tcainternet.com>
Message-ID: <t8b8e5od7auca6@corp.supernews.com>
Source record: 54776

A ham in our club gave me a GR 1603A impedance bridge today. No manual.

Anybody got any pointers on how to use the thing? I assume I need to hook an AF source to the "generator" terminals. The "unknown" terminals are pretty self-explanatory. And I'm not sure about the "detector" terminals. A diode detector and meter movement? Or oscilloscope?

I wonder how useful this thing can be to the typical homebrewer that already has L & C measuring gizmos. Ought to fun to play with anyhow. Tips and resources appreciated.

Hi

Vackar/Tezla and Seiler oscillator types are described in several
notes and articles in CQ, QST, Radio Communication and other since the
50's.
I prefer the Seiler type, because it seems to be easier to oscillate
without too complex calculation, but it was sometimes strange when
Tezla didn't oscillate.
It was a very good article in the Danish magazine 'OZ' in 1957,
describing forward conductance and calculation of maximum shunt
capacitors, seems you could use a 6K7 valve with .01 capacitors from
grid and anode to ground.

For some applications it is no problem that the oscillation level
varies, particularly if you feed the signal through a limiter and a
schmidt trigger, then Clapp oscillator is favoured because of it's
simplicity over the later types.

There's a Vackar VFO and pretty good discussion of it in the 1998 ARRL Handbook. (May be in the latest edition too--I don't have one later than 1998.)

The Vackar oscillator is featured in post-1995 ARRL Handbooks, in the
chapter on oscillators and synthesizers. This chapter is a fresh
approach to the subject, and well worth reading.

The Clapp oscillator is basically a Colpitts oscillator
where the inductor in the low-pass feedback network has been
replaced with a series tuned circuit making the feedback
network a bandpass arrangement. The original publication
is:

J. K. Clapp, "An Inductance-Capacitance Oscillator of
Unusual Frequency Stqbility," Proceedings of the Institute
of Radio Engineers, Vol. 36, pp. 356-359, March, 1948.

> Need some info on capacitor relations for the Clapp-
> oscillator. I am well aware of problems with varying
> output, but tuned frequency range is small, and the 2.2MHz
> signal is fed to CMOS divider for 136-138kHz output.

The ratio of the two capacitors shunting the series tuned
network is determined by the amount of feedback needed. A
typical ratio of 1 to 3 is often used.

> May use BF199 in the VFO, with 10nf between emitter-basis
> and 3n3 to ground, 300pf tank capacitor and 20H coil.
> Could the tank capacitance be larger? Copyed a circuit
> designed by OZ6NF in 1963, for 4.2-4.4MHz, but he used
> AF124 (=2N1744), is actual yfe substantially higher for
> germanium transistors than silicon?

These capacitor values seem somewhat large and reversed. As
a good starting point, the emitter-ground capacitor should
have a reactance of about -j75 to -j100 ohms, or about 1 nF
in your case. The base-emitter capacitor should be smaller;
I would suggest something in the order of 470 to 680 pF.
Using 200 pF as the tuning capacitance, the coil would be
about 26 uH. The BF199 may have too high an f(sub)T for
such a low frequency oscillator leading to VHF parasitic
oscillations. I would consider using a transistor with an
f(sub)T no higher than 30 to 50 MHz for best results. For
high stability, you generally want the tuning capacitor to
be much smaller than the feedback capacitors. So I would

also consider lowering the tuning capacitor value and increasing the inductance.

You're correct that a circuit has to generate power to have a reflection coefficient greater than one. You'll encounter this negative resistance condition in some active circuits such as oscillators or amplifier inputs, where the Smith chart is also used. Also, in some phased arrays, one or more elements send power toward the source, so there's a negative resistance looking into the transmission lines to those elements from the source. The power is, of course, coupled from the other elements. For sure, though, you'll never see a reflection coefficient greater than one in a totally passive circuit.

Hello Lars

You need to help us here. I assume that you have one of these in you possession. I do not have information on the PCIM 177 but do have it on similar modules. Is the large integrated circuit a MSM5527 or something similar? There may also be a pre-scalar, for example a MSL2318. Any part numbers would help.

Please respond directly to me to save newsgroup bandwidth.

My 1998 version of the ARRL Handbook has a schematic of G3PDM's
Vackar VFO. For temperature compensation it uses an Oxley
"Tempatrimmer." Does anyone know what this is, or how to get one?

Hi Tom,

The "Tempatrimmer" is a differential capacitor with the rotor attached to a bi-metallic strip which moves as the temperature changes, like a thermostat. At a constant temperature, you can rotate the capacitor shaft without changing the total capacitance. Temperature change *will* change the effective capacitance.

You use it as part of the trimming capacitance of your oscillator.

The idea is that you start your oscillator, measure the frequency of oscillation, and then after it has completely warmed up, return it to the original frequency with the Tempatrimmer.

Presumably, it will thereafter compensate for temperature changes (between the starting and ending temperatures, at least). This assumes that the change in frequency is linear with temperature, or at least is the same law as the Tempatrimmer.

It works pretty well. I have two of them, purchased in the '60s, that have been re-used several times. They were made by a U.K. firm named Oxley. I don't know if they are in business any more.

Yes, it says, "The Oxley Tempatrimmer used by G3PDM was a rare
and expensive component, used commercially only in very high
quality equipment and it may no longer be made." Later, it
goes on to advocate the use of GM4ZNX' temperature compensating
bridge. Fine, but if that kind of explanation was used thoughout
the Handbook, we simple-minded home-brewers would find ourselves
spending more and more of our time on the psychotherapist's couch

complaining about the purposelessness of it all.

Hi all, I've been trying to find some information on the effects of wire size in toroid inductors. Looking at the formula used to calculate the inductance of a toroid, it seems that the size is not even specified. Does that mean that I would get pretty much the same results whether I was to use #22 or #28 wire?

I'd appreciate any info..

Wire size doesn't change the inductance. It can change the Q due to the change in resistance. The change in resistance between #22 and #28 for the length of wire used in most applications will not have much affect.

Alex,
My understanding is that wire size has little affect on inductance.
It is important in that it will affect how many turns you can get on a
given sized torroid. I would expect that there would be minor effects
on interwinding capacitance and Q. I typically use the largest wire
which will conveniently fit. This will provide the best mechanical
strength and highest Q, all else being the same.

I'm new to electronics and I am trying to build a small FM transmitter. The circut contains a 3-18 pF adjustable cap fo tuning. I can't seem to find any info on how these work. I assume that I turn what looks like a "screw head" inside, in order to change the capacitance. Does one turn cover the whole range, or many turns? Any information would be greatly apreciated

The best one that I have seen so far is the Phillips TDA1572. This is the one that is used in the AOR7030. The good thing about this chip is that it has an AM detector on board, along with its own AGC system. Another good thing is that the 1572 has a buffered 50 Ohm I.F. output, for feeding SSB detectors, etc.
Although it is touted as an AM receiver on a chip, the I.F. and demodulator portions are the most useful parts.
On a final note, I have been using this chip in my own receiver designs for a few years, with good results.

There's different types. If its the type that just continues
rotating with no stop, then the range 3-18 pf will be in 180
degrees of rotation. Lets say you're going clockwise, it will
increase from 3 to 18pf and as you pass the halfway point it will
start decreasing back to 3pf. If you cannot see the moving
plates, its hard to determine where max and min are.
A compression trimmer will have a screw that will usually
"tighten" if you go clockwise 6 or 8 turns. Thats max capacity.

HI Lee.

I think that the capacitor is probably one of those that you just turn it one in order to go from 3 to 18 pf. But just to be on the safe side you can do this little experiment to see if my theory is correct.

Hook up a 50 MEGA ohm resistor in series with the cap and attach it a 12 VAC voltage source. The esiest thing for the AC source is a transformer. If you can get a function generator and set the frequency higher then you could use a smaller value resistor, but the transformer is fine. Now, assuming the frequency of the transformer is at 60 Hz you should get these readings.

When the Cap is at 18 pF then the voltage drop across the resistor should be about 3.86 v. When the cap is at 3 pF then the voltage drop across the resistor should be 0.67 v. This way you will know when the 3 pF starts and when the 18 pF ends.

If you don't get the same values then remember that the higher the value of the cap the higher the voltege drope across the resistor.

WB5DJE ended up using a Seiler type VFO in his 40 meter cw transceiver
in April 1980 Ham Radio Magazine. He wrote:
"I had an interesting experience with this VFO in the design stages.
I started with a Colpitts oscillator, which seemed to work very well.
However, when I keyed the transmitter it shifted by about 650 Hz.
After working on shielding and buffering, and still stuck with a 300
Hz shift, I threw it out and designed the Seilor, which, without any
shielding, shifts only about 25 HZ when the transmitter is keyed and
sounds as if it is crystal controlled."
I might add that I built my version of his circuit using a silicon
capacitance diode and a 10-turn pot for tuning, and mine sounds
rock-steady as well. Highly recommended. 73, David K3KY

Lee,
Sounds like your talking about a 'trimmer' capacitor. If
so, then they usually have a multi-turn adjustment.
'Doc

1011. Re: Wire size in toroids

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-12 12:56:28 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A87DD7C.1A9DC8F6@eznec.com>
Source record: 54707

Wire size makes almost no difference in either inductance or Q of a toroid, within reason. "Within reason" means that hair-fine wire might noticeably lower the Q, and wire so large that it won't conform to the core can lower the inductance and Q a bit. If you've got access to old QST magazines, see "Choosing Wire Size for Toroidal Inductors", in Technical Correspondence, QST, April 1983, p. 39, for some measurements.

1015. Inquiry - HW-101 - No time to play.....

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-12 18:40:31 UTC
From: Curtis Scholl <cscholl@izzy.net>
Message-ID: <3A882E1F.A5027CFC@izzy.net>
Source record: 54711

Hi Folks:

I want to sell my HW 101. I just don't have the time for rag chewing and QSL hunting anymore. I thought I had enough time, but I am more involved with amateur rocketry now and need the time for building tracking transmitters on the VHF/UHF bands.

The 101 is in good condition, works on all bands, 80-10 and may need some tuneup, but I haven't had many problems with it. It was modified by the previous owners by the addition of a power switch on the inside of the upper case, a push button on, push off, to replace a failed original pot switch.

This unit is a workhorse not a pristine vanity piece. And it has "character" in the form of a leg missing on the CW filter switch. The power supply is decent, and the power cable is a rebuild.

Does anyone out there have any desire to own this unit? Please reply by email to cscholl@izzy.net

Thanks

Curtis Scholl

After marketing our wind-up reel antenna for SWL's, several hams have approached us about manufacturing a DIPOLE model. So we've done just that and call it the "YoYo-Tenna Deluxe". We've taken two of our YoYo-Tenna wind-up antennas and combined them into a PL-259 coax fitting. You can add coax...or...just plug it straight into your rig or tuner! 40 ft. per reel, so operation is from 10 thru 40 meters. (One ham suggested "stacking" them...or running them in series to cover 75/80 and 160. I'll leave that up to you guys...) If you want to see what a single reel looks like, please visit our website. - http://qth.com/dwm - Remember, no shipping and handling will be charged on the Deluxe model since you are ordering two...and we give free shipping on two or more YoYo-Tennas. (Total cost - $29.90)

Thanks for your time and 73!

Bill - WA8MEA @ Jackson Co., Michigan QRP Club Station - KC8BCR

The 1603 is a Z-Y admittance bridge generally used at UHF frequencies. It can provide vector measurements of impedance, slowly and painfully. The generator is a UHF signal generator. The detector can be a diode detector. You will then convert the admittance values (shown on the the lever position) to L and C impedance. They still work as well as they ever did. I've been looking for one to show my son how to do basic measurements (not pushing a button and having a number pop up).

Hope it helps

Source record: 54724

LA6LCA is constructing a hgih performance 2m ssb transceiver using tunable 4 stage 4-5MHz IF BPF, 70MHz xtal filter on LO, doubled to 140MHz with no further amplification to feed the high-level diodemixer

I wonder if it is possible to do it the other way around using a super selective 2m tunable cavity filter tuning 144.000-144.500MHz segment

What sort of selectivity can be achieved with 2 stage og 2x 2stage RX filters? I could connect the BPF after the BFT66 pre-amp

Is any information available for possible 2m cavity filters on the web? My operation is mainly around 144.050 +/- 25kHz and 144.275 +/-50kHz, so a compromise filter could have 100-150kHz bandwidth but I would prefer a variable filter with minimum selectivity - provided temperature stability isn't too much problem

Is it impossible or can it be achieved?

Here's what I do. I have one of those 49mhz VOX operated headset units. I put it next to the scanner speaker. Then I can carry my handheld scanner around the the premises, tuned to the 49 Mhz freq and hear the remote scanner. Of course the usual antenna mods can be done to increase the range of the 49Mhz transmitter but in my case it is not necessary.

It would be nice if folks responding to this would remove rec.radio.amateur.homebrew from the list of groups to post it to. Radio amateurs ("hams") call homebuilt equipment "homebrew", so the topic of that group is homebuilt radio equipment, not beermaking. Some hams do both kinds of homebrewing, for sure, but even they post their beermaking questions on other groups.

Thanks, and bon apetit!

Hey all, just finished a homebrew receiver, all BC band only, but lots of fun. Some minor problems, can anyone help me? When I turn 'er on, it sounds like its way "overdriven". The 8 ohm speaker will click and pop like its being overdriven, then if I turn it WAY down, she'll be ok, but of course, the volume is practically nil! Some specifics... Homebrew (as mentioned) uses two UA 741 for amps, connected in series, two small transistors, a 2N3904 and a 2N3906, and some diodes and resistors. Really, that and a variable cap and coil of course, but that's about it! Where can I start? I thought maybe too much voltage or something so I tried decreasing V from 12V to 9V, same thing...Checked and re-checked all values of resistors... BTW, dunno where I found the schematic, but I designed a PCB for it. Was loads of fun..... Would be happy to send specifics or even schematic if you felt it would help..

Hello,

I am considering building the 2m 25w Brick amp that is shown in "The ARRL Handbook 2000" on pg 13.44. The amp uses Toshiba's S-AV7 power module. I was wondering if anyone has built this amp., and what there experience with, and thoughts on it are.

Also, does anyone know where I can find the S-AV7?

TIA,

David Johnson

According to some old (1994) brochures from Sinclabs, their
SBP-144-4N1 four cavity bandpass filter had a 1 MHz bandwidth with 2.1
dB passband attenuation (and thus usable only after a preamplifier :-)
and the response was down at -90 dB around 120 MHz and 153 MHz.

Cavity resonators usually have spurious responses at frequencies very
far away from the intended frequency f, typically at 3f or 5f, but
unfortunately none of the published graphs extended that far.

Apparently this is some miniature design, since the dimensions were
only 64 x 216 x 280 mm, while a full size 1/4 wave construction will
require about 500 mm.

Typical full size repeater cavities are usually configured as bandstop
filters, but apparently at least some could be configured as bandpass
cavities as well.

It would be desirable to have an as high unloaded Q as possible, since
the unloaded Q / loaded Q ratio determines the passband attenuation
and the loaded Q of course determines the passband width. Apparently
each of the four cavities in the example above, had a Qu/Ql ratio
around 15, thus the unloaded Q would have to be in the order of 1000
.. 2000 (it is a bit hard to estimate due to the interstage coupling
in a multiresonator design).

Bury the resonators in the ground and the temperature will not vary
too rapidly :-).

I've got an otherwise pretty useless Icom R-1 wide coverage receiver I use as the detector. A diode or similar untuned detector is fine if you're working indoors on physically small items. But when you measure an antenna outdoors, your antenna is picking up all sorts of signals from TV and broadcast stations, paging transmitters, and the like unless you really live out in the sticks. The diode detector will merrily rectify these as well as the applied signal, giving you bad readings or a total inability to get a null. You have to use a tuned detector like a receiver to prevent this if received signals are a problem. If the interfering signals aren't too close to the frequency you're testing at, you can get by with a simple detector preceded with a tuned circuit, bandpass filter, trap, or whatever is necessary to separate them.

Some years back I rented a very expensive digital HP impedance meter for a consulting job. It was super on the bench, but just about useless trying to measure a vertical because of very strong AM BC reception. I ended up using a borrowed ancient tube type bridge that had a preselector ahead of the detector. The 1603A I have now works fine for antennas as long as I use the receiver as a detector (preceded if necessary by filters and/or attenuators -- the R-1 front end crunches very easily).

Source record: 54733

Tom Bruhns dropped me a note pointing out that the magnitude of the reflection coefficient can indeed be greater than one in passive circuits. Apparently Reg also mentioned this in a posting, which I didn't see or I overlooked. My apology for missing this.

I'm going to use rho to mean the magnitude of the reflection coefficient, not the complex reflection coefficient itself, here.

It turns out that the condition for rho to be greater than one at the load is simply R * R0 + X * X0 < 0 where R0 + jX0 is the transmission line characteristic impedance Z0, and R + jX is the load impedance Z. When doing analysis at HF and above, Z0 is almost always assumed to be purely real, because it is very nearly purely real for ordinary transmission lines. (An exception would be ones which are much lossier than would normally be considered for common uses.) When Z0 is purely real, X0 is by definition zero, so the only way that the condition for rho to be greater than one can be satisfied is for R to be negative. (Negative R0 could also do it, but this could surely never happen with a physical transmission line.) Consequently, it's common to assume, as I did, that the only way rho can be greater than one is for R to be negative, which can't happen in a purely passive circuit.

But when Z0 is complex, even slightly so, rho can indeed be greater than one, and it's easy to find combinations of Z0 and Z that'll make rho greater than one while maintaining positive R and R0.

Again, my apology to Reg for missing his reference to this, and my thanks to Tom for getting my attention and pointing it out to me.

2 Opamps in series ? What's their individual gain?
One opamp would be more than adequate even with reduced gain.
Suggest you try this first.

I think you read DUBUS, so you could use the crystal resonator
from my oscillator article in the nov 2000 issue.
Just rise the impedance level to get less attenuation and
wider bandwidth, although 150 KHz BW is probably a little bit too much.
7th overtone crystals should get you easily to 144 MHz.
I´m going to try that soon.

Collectors of European equipment typically would prefer the original tube
and reserve the diodes for instances where the tube cannot be found.
Remember, with diodes you must always add power resistors in series to
compensate for the loss of forward dynamic resistance.

Wire diameter has an insignificant effect on toroidal inductance.

It has a monor effect on self-capacitance and hence on the self-resonant frequency.

Thin wire has a higher loss resistance. When wire loss exceeds core loss a further reduction in wire diameter causes a decrease in Q. In most cases of close wound windings the ferrite core loss predominates.

Download program TOROID from website below. Amongst other things it calculates maximum wire diameter for given number of turns on a core of given dimensions.

Tom:

When you have put so many hours into the construction of a device, and are having problems, you need to get someone else to look at it for you. I don't see any way to do that on the internet.

Do you have a ham friend who can check your circuit board layout and wiring? If so, he/she may see something that you are not.

On the assumption that the original design was technically sound, there are only a few possibilities:

1. You have an error in circuit board design
2. You have a bad component
3. You installed a component (or components) in the wrong place

The fact that it is at least partially working means you probably only have one of the above problems.

I am sure you have checked and rechecked everything several times, but a fresh look by someone else can do wonders. (Don't ask me how I know this.)

Good luck,

Roger K6XQ

seems the diode detector in my instrument is defective. The manual
doesn't show how it is arranged, does somebody have any info on this?

Hmmmmm. Symptoms sound like the audio section is 'motorboating'. If so,
find the circuit that feeds the speaker (I assume its one of the 741s) locate
the pin(s) that supply power, break connection, insert a 10 to 100 Ohm resistor
in series, and a 1 to 50 uF cap on the supply pin to ground. Ideally this
should be a tantalum cap, but an electrolytic may do. Post if there is any
change in performance. Also, if you post me a skez, I could better assist.

1050. DSP IF or Analog?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-14 00:24:55 UTC
From: baby HUey <na@na.na>
Message-ID: <l7ki6.91$fm6.65151@nnrp3.sbc.net>
Source record: 54597

I'd like to understand the pro's and con's as well as ideas on this. I am working on the design of an HF receiver for AM, SSB, CW. I am thinking about heading down the IF DSP for flexibility etc. I'd like to hear opinions as well as design considerations for such over standard analog implementations.

Thanks in advance...

1051. help, need info on plate curve computations

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-14 00:40:49 UTC
From: hexter@blazenet.net
Message-ID: <t8jl0hlu1aef6c@corp.supernews.com>
Source record: 54598

I must be missing something,

Years ago, and even a few months ago, I have built some differant styles of amplifiers. Some rf, some af, a few watts, to a few hundred watts, and my question is this,

What good are constant current curves? I use and understand the transconductance curves with plate voltage at the bottom, and plate current up the side, but geez, when I get spec sheets from svetlana, or eimac, they are the 'constant plate current curves'. I see no easy way to plot a load line, or make any useful calculations to determine voltage swings in the load, etc.

Should i ask for a differant curve sheet? Do they still use transconductance curves for design? Why the big interest in 'constant current curves' anyway?

I thank you for any help that is given. Post to the group as
1 my addy is totally bogus to foul spammers,
2 probably, others want to know this answer also.

1052. Re: DSP IF or Analog?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-14 00:52:57 UTC
From: Piotr Balcerzak <bpiotrek@yahoo.com>
Message-ID: <JFki6.243234$JT5.8682722@news20.bellglobal.com>
Source record: 54599

Pros:
1. easy to modify (most of the receiver circuits are implemented in
software)
2. repeatability of performance (doesn't make any difference for one-time
construction)
3. very sharp IF filters with decent phase and attenuation characteristics
3. decent detectors (AM, SSB, sync AM)
4. programmable AGC action
5. auto notch
6. "denoiser"
7. additional features (RTTY, SSTV, etc... decoders)

Cons:
1. DSP requires mathematics, mathematics and mathematics
2. AGC range limited only to 40-50 dB assuming 16bit ADC (remaining
50dB must be implemented in analog way)
3. hard to remove hum (a huge work on proper wireing and shielding)
4. more mathematics skils required to write good software

As for DSP absolute basic skils required are: binary arithmetics,
precission, etc...,
FIR/IIR filters synthesis, Fourier transform, "Z" transform, scaling
techniques in
frequency and time domains, PID loops, trigonometric functions and how they
describe signal mixing. And deep understanding of how radio blocks work
(mixer,
noise limiter, detector, etc.). And how to connect digital and analog
circuits altogether
avoiding noises. (Look at NRD545 and its screwed up IF filter and very
"peculiar"
work of tone control. Then look at WJ HF1000 specs...)

Anyway, DSP is well worth to try. If I wanted to build HF receiver I would
very likely choose DSP.

Good luck with your project!

Source record: 54602

Hmmm ... thanks for feedback Keven (and other posters). But now I'm confused at a higher level. I would have thought for sure that it was for use at audio frequencies. The input is labeled "Operating frequency 0.020 to 20 kcs" and some switches labeled "for direct reading" select 0.1 kc, 1.0 kc and 10 kc.

I looked inside. Some mica caps and ceramic trimmers, but also several big (2 in diameter by 3 in long or so) electrolytics. I think these oil filled caps may have done a bit of seeping. Which makes me wonder--if I should have to replace them, would the replacements have to be precision types. (Never heard of a precision electrolytic or oil filled cap.) I guess if that's the case I'd better stop while I'm ahead.

1056. Class A,AB1,AB2,C RF Power Amplifiers

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-14 01:18:37 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <96cmav$qq1$1@neptunium.btinternet.com>
Source record: 54603

NOW AVAILABLE :

New Program "TETRODE1.exe"

CLASS A, AB1, AB2, C OPERATION OF TETRODE RF PA's

Obtain a minumum of info from a tube (beam tetrode or pentode) manufacturer's data sheets or curves. Enter in program with DC anode supply volts, DC screen volts, minimum anode volts, maximum control grid volts, required operating angle, intrinsic Q of tank coil, required working Q of tank circuit, frequency.

A useful feature of this program is direct entry by the user of the anode current operating angle. This angle controls the various combinations of linearity and efficiency.

An important data entry item is the control-grid to screen-grid amplification factor, Mu. If the manufacturer's value is not available it can be guesstimated by varying it until other characteristcs become compatible with what info there is available.

The program computes RF power output, anode loss, screen grid loss, tank coil loss, DC-RF power conversion efficiency, peak and DC anode current, DC screen current.

Also tank inductance, tuning capacitance, turns ratio for link winding to 50-ohm load, source impedance looking back into 50-ohm output terminals. Note that a congugate match does not exist at this point.

Grid circuit conditions are computed:- peak RF drive voltage, negative DC grid bias, input impedance, drive power, DC grid current, grid bias resistor, grid current operating angle, grid dissipation.

Covers power outputs from QRP to 100KW.

Push your own precious and delicate linear up to and beyond its safe working limits without any fear of accidentally blowing it up.

Highly educational even if you never use this program in anger.

Download in a few seconds from website below. 52 kilobytes, 1 file only, not zipped up, run immediately.

Greetings all

I notice that in the surplus Toroids that are available the cors are painted colors probably to identify characteristics. Is there any INFORMATION available to identify the colors as to what characteristics each color may have?
Also I have one core with numbers "A 050056-2 BH4+5" any help at decoding this?
Can anyone point me in the right direction to find INFORMATION? or?

color me curious.....

& Thanks

I confused you. My only excuse is that I'm brain dead and home enjoying a virus. The 160_2_ is the admittance bridge. The 1603 is an audio bridge.(you knew that) GR sold a null detector to indicate the bridge balance (1232A- I cheated and looked it up). The catalog says the detector has a gain of 120 dB and 0.1V sensitivity. My apologies. I'll try to get a better drug mix.

Depends totally on the equipment :-)
If it's a late-sixties home-brew receiver made up of parts from a large period

of time I probably would do this to free special parts for another project.

Interestingly, this is also what's used to cool the 15 kW arc lamps found in the larger IMAX film projectors. The lamps produce the arc between two tungsten electrodes in a xenon atmosphere (probably along with other gases). The electrodes extend many inches into the bulb, and there are water cooling passages inside the electrodes. Changing a lamp involves plumbing as well as electrical connections.

Since the water is in direct contact with the metal of both electrodes of the lamp, and there's only one cooling water circuit, if the water had any significant conductivity it would provide a current flow path that would bypass the lamp. Not that anyone is worried about diverting much current from the lamp (it runs at something like 200 A), but much current flowing through the water could cause a lot of corrosion.

In addition to the lamp, there are other water-cooled parts. There are two beam-folding mirrors which are "cold mirrors" - they reflect visible light but infrared goes through the mirror into an aluminum backing plate, which is water-cooled. And the shutter that blocks the light from the film while the projector is not up to speed is also water-cooled.

Tom, you failed to mention if it is TRF,regen,hetrodyne or what...it is probably TRF, in that case you could have a mistake or fault in the rf amp section which would give you weak rf and you would need excessive audio to hear the signals at all .if the audio works you need to look at front end only ,OK good luck.. >away.

I just feel a need to support my own company here, i.e. I work for Cray Inc.
They're still around and still selling quite a few machines.
They do look interesting although the older models had more visual appeal IMHO.
Fluorinert (sp?) is still the standard liquid used in our liquid cooled
machines as far as I know.
Newer machines have lost the semi-circle layout and look alot more like
a collection of boxes. Cool boxes though :)

Enough babbling from me now. If you want to know more, go to www.cray.com.

The bad news - iron powder toroids are painted to indicate the mix, and hence the permeability and frequency range, but there is no standard. Most of the toroids in amateur radio use come from Amidon, and they have 2 color schemes, one for amateurs and one for industrial use. Ferrite toroids aren't painted at all.

If the ferrites were scrounged from some equipment manufacturer's inventory, there is a good chance the numbers you have are from that manufacturer, and maybe even the colors.

If the toroids you have are mostly red and yellow, there is a good chance that they are from ham radio stock and are probably -2's and -6's. White (-7) is also fairly common. Other colors are rarely used in amateur radio service.

The good news is that it's not too hard to measure the permeability. Simply put say 10 turns around the thing, put it in series with a resistor or cap, apply a few volts of RF across it, and measure the RF drop across the toroid and the other component. You now know the reactance, and hence the inductance. Unfortunately, this doesn't tell you the loss. Toroids have useful frequency ranges, too. Outside that range they tend to get lossy. The -2's are good from 2-30MHz, although they are generally used only below 10. They have a higher permeability than the others, and at the lower frequencies you are generally looking for more inductance. The -6's are good from 10-50. The -7's from 3-35. The -7's have a better temperature coefficient than the others so they tend to be used in VFOs.

The ferrites are all a shiny black and can't be told apart by eye. They have a much higher permeability than the powdered iron ones. In general, they are only used in resonant circuits at very low frequencies, most are only good below 1MHz. However, in transformer service, they aren't so frequency sensitive, so you find them in chokes and transformers.

Oh, the handbook is the reference for hams, but the Palomar Engineers web page has the colors for those intended for ham service. But for 99% of the powdered iron toroids used in amateur radio service, there's not much to know:

freq u ppm/degC
Red -2 2-30 10 95
Yellow -6 10-50 8 35
White -7 3-35 9 30

hope this helps

Is it possible to extend the range of the rit/xit on the TS830, I assume the range is dictated by the characteristic of the varactor/varicap diode and the pot. It would be great to be able to increase the swing to +/- 5kHz.... any thoughts pls?

1071. PSK-31 On A TS-450 Under Computer Control?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-15 02:59:42 UTC
From: n5kzw@iname.com
Message-ID: <3a8b43be.13512315@news.infohwy.com>
Source record: 54618
Cross-posted to: rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew

I would like to operate some of the digital modes on a TS-450S while at the same time having the computer in control of the rig. YPLog appears to support this, but I'm having trouble with the I/F.

I built up the soundcard I/F using isolation transformers and an opto-isolator to connect the rig and the computer through the 13-pin DIN connector and the serial port. The I/F works as advertised.

I also bought the W1GEE I/F to control the rig from the computer, and it also works as advertised.

The problem is that I want to use both of them at the same time.

The PSK-31 I/F wants to use RTS or DTR to key the transmitter, but the W1GEE uses both of these signals when talking to the rig. Also, the PSK-31 I/F takes great care to isolate the rig ground from the computer ground. The W1GEE I/F ties the two grounds together.

Has anyone done this on a TS-450S successfully?

Thanks,
Ed - N5KZW

When it is less, one might make desires what is better, but it may be
worth considering what is really needed.

Since the FT-902 already has +/-5kHz on all modes, I experienced this
was too much for large part of my activity, so I modified the RIT
range dependent on the mode, +/-1kHz for CW and +/-5kHz for ssb
(unmodified)

If it had been possible I would have chosen ranges as shown below:
HF SSB +/-5kHz
HF CW +/-1kHz
2m CW MS 5kHz
2m CW +/-2kHz
2m /70cm SSB +/-5kHz

very seldom you need +/-5kHz. On CW as on SSB the RIT is only needed
to compensate for drift, and in ring-QSO's - for different tuning, so
normally 0.5kHz range is quite satisfactory

Dennis,

Depending on the kit, you might consider the following.

Multimeter - digital will be OK for most applications. Get one with a FET input circuit so you have a hi-impedance meter.

Buy a good soldering station. It will certainly represent the centerpiece of your workbench! Good soldering station are available at decent prices all the time. Join the QRP List.

Forget about the PC board vise. For your first kits you can make do with your workbench! PC board vises are a luxury and don't contribute much to the construction of a simple kit!

Dear Curious,

There is NO standard for toroid color coding. Let me repeat that - THERE IS NO STANDARD FOR TOROID COLOR CODING. You can only depend on color coding from a single manufacturer and even then you may be up against special runs.

Torords are CHEAP. I'll repeat that too - TOROIDS ARE CHEAP. Go to Dan's Small Parts and you will find assortments of toroid cores by Amidon. Go look at the Amidon web site (www.bytemark.com) and they will have lots of core data and also sell their cores.

Don't waste your money on surplus toroids unless you are a dyed in the wool experimenter who does not care what he has!

From: n5kzw@iname.com
Message-ID: <3a8bf4bb.5903509@news.infohwy.com>
Source record: 54625

I just got done making up an I/F for a TS-450S that used a 13-pin DIN connector from Digi-Key. It was a real pain trying to solder wires to the bare pins on the back of the connector. I have to believe I was doing something wrong.

Are there some sort of slip on contacts that you solder your wires to before they are pushed on the pins? Is there some sort of wire-wrap arrangement to wrap the wires arount the bare pins?

Hi all,

I need some input on the Drake L7 HF amp. I can't find much in the way of reviews, complaints, etc. on the amp (online). The nice look of the amp and a few other things caught my eye and I was thinking about purchasing one. What are the pros / cons of this amp? Would I be better off with a Kenwood TL-922A ?

I have looked at the online Drake muesum already.

Thanks,

Scott.

It helps if you cut about 1/2 inch of insulation off the wires and tin them. Then cut the wires very short. Then move to the connector. Put a little solder in each pin. Then you heat the pin tuil the solder melts. YOu then place the wire next to the pin and let the solder that is already there plus the solder on the wire do the job without adding any more solder. Hard to explain, but simple to show how it is done. YOu do need some kind of vise to hold te plug so the pins are vertical. That is the plug is up and down and not horizontal like it would be if plugged in the rig.

interesting approach, but seems odd to choose transverter from 6m to
2m.
Usually, if one like homebrewing one doesn't already have 6m, only
those plastic radio enthusiasts seem to to have 6m, as a part of
theplastic toy, but won't build a transverter to go to 2m

My 6m transverter uses 20m IF instead of 28MHz, because I would avoid
2x 28=56MHz problem

Something that works for me...

Get 2 DB9 female connector kits from Radio Shack. These connector kits contain a DB9 shell and a strip of 9 crimp sockets on a strip.

Using a vice to hold the connector, lightly tin the posts to which you intend to attach wires.

Attach the DB crimp sockets to the wires.

Plan ahead and start with the inner posts. Push the socketed wire end down over its post. With a pencil iron or other fine tip soldering device reflow the solder on the post you just pushed the socket onto.

I typically use a piece of heat shrink tubing to insulate the connection (after the pin has cooled).

If you rummage around on this web site, you will see exactly what Bruce said (and I didn't say so loudly) -- 'THERE IS NO STANDARD FOR TOROID COLOR CODING.' On this one web site there are at least 2 different color schemes.

I agree with Bruce that toroids are cheap, and I try to keep a good supply of those I commonly use. They are cheaper at Dan's, as Bruce points out, than pretty much anywhere else. But if you need just a few, it generally works out better to order them at radioshack.com because of the shipping (although it's hard to look through Dan's website without finding $100 worth of stuff you can't live without, and for that kind of order his shipping deal is better than radio shack's.)

But I disagree that it's important to throw away the junk ones. It's not so tough to measure the permeability, and as long as you are suspicious of the loss, why not? Obviously, it depends on how critical your current project is, and how much you value your time. Just don't get suckered into believing that because it's white it must be a -7.

Hi Ed...just saw your name/post. Long time no see!!

I saw a similar post on the Kenwood list and one response was to clip out all the unused pins. Kind of "bad" for the long term, but if you know it's not going to change, seems to work. We had a devil of a time on the cable for our TS850 as well!

Good Luck and maybe we'll see you at Belton!!

Help
I need some info or a circuit for the demodulator output of a Wandel & Goltermann SPM-6 selective level meter, 6KHz -18MHz. The demod output didn't work when I got it and on tracing the coax cable from the demod board to the rear panel I found it crossed over as it went through a multi way connector thus shorting the demod output to ground, I've fixed this but need the output stage circuit to fix the final stage - any help appreciated.
Also does anyone know what the BNC output on the back to connect to an FFZ-6 is
for? and is it easy to get an IF output pre-filter from the unit as I want to use it as a receiver and the 1.4KHz BW is narrow for AM.
The SPM-6 may be known as something different in some regions, I can't find many references to it but see ATxxx which may be similar - mine has a mechanical frequency readout.
I would appreciate email replies as my ISP seems to loose a lot of newsgroup messages making following a thread totally impossible.

Many Thanks

John

==========
When confronted with soldering connections on multi-pin plugs and socket I always use rubber sleeves completely covering the soldered point/pin. This is a very reliable way to ensure separation in 'wire crowded areas'. So far I have been using the sleeves from scrap wiring/equipment .

In the UK Maplin sell Helsyn binding sleeves in 20-25 mm length ,diameters 1.5 - 2.0 - 3.0 - 5.0 mm costing approx. equivalent US$ 2.50 for a pack of 100 pcs.

The larger diameters are also effective to bundle wire runs inside equipment.

To keep to basics it would be better and more likely to succeed by constructing a separate receiver and transmitter. First complete a simple receiver for one band only. Then start on a one-band very low power transmitter.

In the UK you do not need a receiving licence. To transmit you will need a transmitting licence. Consult your science teacher or a local radio amateur club.

My friend, Dave, G3YNH, is constructing a polarisation rotator for a
12 element ZL-special 2M antenna. He is using a gearbox from a
pre-war wind-up gramophone and the motor from a 35mm camera.
The motor runs on ~3 volts and is about 2cm x 3cm. with a 3000:1
reduction gear it can turn 180 degrees in about 30 seconds. It is
powerfull enough that you can't stop it bare-handed even on a
4" diameter wheel. It would certainly work as a conventional
rotator for 2m yagis of 12 elements or less.

The project is near completion and will be on the web when
finished, at

http://www.camuw.demon.co.uk/web_site/g3ynh/g3ynh.html

Not there yet but coming soon!

best

Andy, M1EBV

Tom,

Traditionally, service quality signal generators did not have very accurate calibration. I have the Precision Instruments RF and Sweep generators that I use for alignment, and they are not that accurate either. Your best bet is monitor the output of your generator with a frequency counter.

For general service, one usually doesn't depend on the generator accuracy unless it is very sophisticated synthesized type. You use the generator for rough alignment, but set the receiver oscillator by tuning to a signal on a known frequency, such as a known AM station, or in the case of shortwave, WWV.

In the RSGB Technical Topics series from 1985-1989 there were a number of snippets published concerning the use of "dirty DC" (not purely rectified and filtered DC), that seemed to be able to charge (numerous cycles) standard alkaline batteries, which of course, the manufacturers claim can not be recharged. There was one rough schematic published but no details of voltage and amps recommended for such charging. Does anyone out there have any more details, or has anyone tried it?

I often recharge alkaline cells with pure DC from my 13.8V power supply.
You must limit the current to a safe value. I use a 100 Ohm resistor in
series with four AA cells. This limits the current to about 78mA.

The first time you recharge them, you will probably get just as much
capacity as you would get from a new battery. When they have been
recharged four or five times, the capacity tends to reduce.

I have never had any problems with exploding or leaking cells but
be careful! you don't want the innards of an alkaline cell splattered
all over your face or inside your digital camera!

Hi Lary.
Set the zener to a higher value.
Most 12 to 13 volt equipment is able to handle 18 volts.
The crowbar is just to protect the equipment connected to the supply
should the pass transistors in an analog supply , or the control circuits
in a switching supply , fail.
Then the output goes to the rail of the buss maybe as high as twice the
normal output voltage. You want the SCR to catch that massive failure and
not just transients.
Also check the filter cap on the SCR gate. Should that fail , impulses
would trigger the SCR.

Ron

Hi there,
Sounds like a classic Palomar Skipper 300 amplifier or one of the later productions units sold under the numbers label like the "321." Yep, they use the hard to find 8950's, a beam power "sweep" tube actually designed for RF Applications. Swan and Siltronix radios/amplifiers also use them and this is a great place to throw out a cheap plug for my Swan Siltronix web page.
-
http://sonic.ucdavis.edu/siltronix
-
: of the tubes are less than 30% on my tube tester. After some research, I
: have found that these tubes are extremely hard to find and when you do
: find some, they are usually used and very expensive. My question to you
: fine intelligent people is "Is there a replacement tube of similar
: characteristics that I can substitute for the 8950's or maybe a
: modification that can be done to allow the amplifier to use another type
: of tube?" After doing my research, and correct me if I am wrong, it
: seems the 8950 tubes use a 12VAC heater voltage instead of the normal
: 6VAC. Any and all help is greatly appreciated in advance.
: Sincerely,
: James, Owner/Operator
: Eagle_Tronics

The only "real" close cousin of the 8950 is the 6.3 volt 6HF5 tube. The conversion article is mentioned on my web page. No, the 6KD6 is not a direct swap in like the other guy posted. If one were planning to rework the amplifier to different tubes, I'd consider the Svetlana EL-509 which may not fit in the original case without some metal working or standoffs.

Your other hope is hours on Ebay looking for tubes...

Being in the UK, I would urge you to contact the G-QRP club
(http://www.btinternet.com/~g4wif/gqrp.htm), and/or George Dobbs, G3RJV.

The G-QRP club has hundreds of designs for simple rigs, many of the simpler ones designed by George. They also have some kits, and sometimes have some of the harder parts for sale. One problem you have is that many of the designs you will find on the web are designed in the U.S., and often use parts you can's get easily in the UK. Also, George is a heck of a nice guy and worth meeting just because.

The G-QRP club has a book called the 'G-QRP Club Circuit Handbook' which has a lot of ideas in it. Well worth picking up.

Also, EI9GQ's designs are nice and tend to feature parts that you can easily get, although a lot of his stuff may be a bit elaborate for a first go.

I have a Drake L7 and would not part with it. Drake runs the 3-500Z's conservatively. You are unlikely to ever see 1500 watts output on any band- 800 to 1200w is more likely. It is a nice-looking, compact amp. Mine has been extremely reliable. I believe you would see a little more power output with the Kenwood TL-922. I would still choose the L7 anyway. 73, David K3KY

Hi
I have 2 power supplies that are from RV campers.These are used to supply 12v dc for the lights and water pumps in the camper trailers, as well as charging a 12v battery.Both of the ones I have are rated at 40 amps 12v dc output. Is there a way to filter the output, and possibly add an over voltage protection so these can be used as power supplies for radio gear? I sure could use a 40 amp supply, and would like to be able to put these to use since I have them. I don't have any camper trailers, so I have no other use for these. I'm not a tech, so I can't get to technically involved to understand making these work for my situation. They have nice big transformers, so it seems possible to use them. I do not know if they use full wave rectifiers on not.So I may need to add full wave rectifiers. As you can see there is a lot I don't know. But if I can possibly make this work, I'd really enjoy the project, and get good use out of something I have laying around.
Thanks for reading. 73 Rob.

Perhaps the simplest way to do it would be to use an RV battery for a filter. But if the supplies don't have some sort of regulation or control to prevent them from overcharging the battery, that's not such a good idea. The concept of turning them into pure DC power supplies is fairly simple, but the right answer depends on quite a few variables: just what voltage does the transformer put out? Do you need a regulated supply, or just a well-filtered one, for what you will be doing? Will your load be reasonably constant, or go from zero to full load? Certainly it should be possible to use the transformers, and perhaps the included rectifiers (which likely are full wave...more efficient use of the transformer, and diodes are cheaper than transformers). But a single "right" answer doesn't pop right out at me.

Cheers,
Tom

1110. Free carbon comp resistors

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-16 19:56:09 UTC

Free resistors? Yes. What's the catch? Well, I've been hanging onto all the old carbon comp resistors I scrapped out of stuff, got in grab bags, and so forth for many years. A couple days ago, I went through them and measured them. I found that many of them are now higher in value than their color code. I tossed all the out-of-tolerance ones into a box, and have about a pound of those. That's quite a few resistors--in the hundreds! Any that were grossly out of tolerance or obviously "noisy", I tossed in the trash. The culls are all 1 watt and above (so far...haven't started on the 1/2W ones yet), and cover from below 10 ohms to a megohm or so. They are marked 5%, 10% and 20%. Typically, the 5% ones are within 10%, for example. Many of them have never been used, but most are "removed from equipment."

Anyone interested? $5 to defray postage & my trip to the post office (or pick up in the Everett, WA, area).

Cheers,
Tom

You could, however, use one of the switcher IC's which take an input from, say 8 to 15 volts, to a regulated output of 12 volts -- something like the LM2577-12 with an external transistor (probably a bunch of PASS transistors). This would accomodate the fluctuation in input and would not suffer from the dropout of a linear regulator.

It goes much further back than that. Sometime in the first half of the 1960s, POPULAR ELECTRONICS published a construction project for such a device, which was claimed to do a partial job of recharging zinc-carbon cells. Nothing tricky about the circuit, it had a 6.3-volt filament transformer followed by a silicon half-wave rectifier that was bridged by a resistor, giving what you call "dirty DC". The total charging current was 150-200mA, controlled by a series rheostat of a couple hundred ohms. I still have in storage the one I built.
I ended up putting a stack of six "button" ni-cads, inside a paper insulating tube, in that machine's D-cell holder, and using it as an UPS for a portable radio that normally took five C-cells.

>to send direct email remove "fake" from address

I have been experimenting with recharging alkaline batteries
these last few months, and have been a little less than impressed.

I have a walkman type portable CD player that is a bit battery
hungry, and I have two sets of four batteries that I have been
re-cycling. I charge them at a slow rate of about 20 ma, as anything
higher seems to cause them to leak out a coffee colored corrosive
substance. After what I consider to be a full recharge (inputting
about 150% of the rated output watthours, the batteries only seem
to be able to supply about 1/2 of their original output capacity,
and they seem to have a higher internal resistance which makes them
unsuited for high current drain devices.

I am all for reuse of batteries, and hate to see millions upon
millions of batteries in the land fills every year, but my personal
luck with re-charging alkalines is not impressive. I suppose if we
could get one or two extra uses out of the cells we could really
cut down resource usage though. Bet the battery companies don't
want to hear that!!!!!

The magazine must have been called just ELECTRONICS then, for you've described exactly the little circuit in the article "Dry cells can be reactivated" by Ralph W. Hallows on page 49 in the December, 1956, issue.

Unfortunately, I can't cite the issue or even the magazine, but another article published about the same time used ordinary LAMPS as resistors, with a small lamp (10-20 watts) for the reverse current and a larger lamp for the forward current (I use 40, 60, 75, or 100 watt bulbs, depending on the cellsize I'm charging). The light from the lamps also gives a visual indication that my charger has cells in it so I don't leave them in too long!

It sounds as the 741s might be oscillating. If you don't have decoupling networks on them, try putting a 22 Ohm resistor in series with the V+ lead to each of the 741s. Next, connect a 100uF capacitor, in paralles with a .1uF capacitor from the V+ pin, as close to the pin as possible, to ground. If you are using a bipolar supply, decouple the V- pin in the same manner. If you don't have a ground plane on your circuit board, that could also be a contributing factor, but the decoupling networks might be a remedy.

Message-ID: <K3uj6.103$mv4.957@newsfeed.slurp.net>
Source record: 54667

Hi, all concerned:

I have a few unused, tested surplus predriver #1 boards, C 3988W, from the Drake TR7, which have 50-ohms in/out (solder posts), 20+ dB of stable adjustable gain from 100 KHz to above 50 MHz, and take 12V power.

I have used them as QRP osc-amp xmtrs, sig gen amps, i-f amps, several on my small loops as low-noise preamps on 160-10M, etc., etc., etc. They worked fine on a very short-lived (one evening) quickie Beverage, as well.

They have gain-adjust pots in the second of 3 stages: 2N3563-SRF2281-SRF2281.

Board is 2-3/4 X 3-3/4 in.G10, and less than 3/4-in. 'thick'. You supply 2 clip-on heat sinks for the '2281s.

Any one interested at $17@ ppd?

Copy of schematic included.

1122. ???HF Remote Base Controller Recomendations???

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-17 17:30:03 UTC
From: "Thomas M. Alldread" <tma@mail.island.net>
Message-ID: <o8dt8tkr3nr19c2hjunirih2l6k76rlgst@4ax.com>
Source record: 54672

Greetings to All on this List:

A group of us have just started to look at setting up a 440MHz repeater as the nucleus for an HF remote base system. Ultimately we want to link this system to a 2M repeater to provide VHF access to the HF remote base as well. We currently have a couple of modern ICOM HF rigs within the group to choose from that we would like to use for the remote base rig. It has been already decided to use Motorola equipment for the UHF repeater and full duplex link equipment with commercial antennas and duplexers.

We have not decided on the controller equipment to use. I would like to hear recommendations from those that have experience with setting up a similar HF remote base system. We basically would like to be able to remotely DTMF control all the serial port controllable features of the HF rig, to remotely select antennas, to remotely control at least one antenna rotator and to be able to keep tabs on the status of the site. Digitally generated voice confirmation for all the remote commands would be needed for feedback to the operator.

Although I have done some Internet searches I have not yet recognized an off-the-shelf controller package that will do the whole job. A friend of mine set up a similar remote base about a decade ago that used a Commodore 64 with a custom interface that does pretty well everything we need but I am wondering if there is a more modern alternative. Are there modern embedded controller systems available for this application or alternatively a PC software package possibly using a pair of sound cards for audio interfaces available off-the-shelf? I guess basically I would like to identify all currently available modern controller equipment packages that are designed to do the job and hear recommendations plus pros and cons from those that are experienced with HF remote bases.

Thanks in advance for all your help!

73 & Enjoy!
Tom, VA7TA
Very Best Regards,
Thomas M. Alldread, tma@mail.island.net

Pick up one of the HP 5328A's that are going for abt $125 on Ebay. Make sure it has the high stability timebase and you have an excellent counter good to 500 mhz. Much more accurate than anything you mentioned.

For under $ 400 you should be looking at a used service monitor. They sometimes show up on ebay and hamfests.. I bought a used Singer for about $ 200 a few years back. While It won't count the frequency you can set the dials to the frequency desired and there is a zero center meter you can watch to see how far off you are from where the dials are set. The sensitivity is also much beter than a counter. It will be accurate at around 2 microvolts where the counteres need about 20 milivolts or more. There are some counters made by Optoelectronics for around $ 100 and as long as you keep them at a reasonable temperature they seem to be stabel and accurate enough for most work. Lots of used comercial counters are out that should be in the under $ 100 price range also.

Try this guy: http://www.xs4all.nl/~barendh/Indexeng.htm
I've used him and he was very prompt (I received my stuff in about 1 week!)
Note that prices are in Dutch Gilder and include %17 sales tax which wont
apply to you.

Regards
Murray - VK6HL

1136. Re: ???HF Remote Base Controller Recomendations???

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-18 02:29:09 UTC
From: Richard Karlquist <rick@area.com>
Message-ID: <VrGj6.2811$5M5.232165@news1.frmt1.sfba.home.com>
Source record: 54683

I have been researching this topic for several years and I think I can
fairly definitely say there is
no totally satisfactory solution to this problem. The only solution
approaching a turnkey operation
is the Kachina. The disadvantages of it are that you have to lay out $4000
for a transceiver and accessories
that has second rate performance, made by a company with luke warm
committment to the amateur market.
The Kachina also suffers from inferior digitized and compressed audio. Of
the conventional
HF rigs, only the Kenwood TS-870 is really easily remotely controlled. I
have an FT-1000 that can be
controlled locally via computer, but is difficult to control via remote
link, and you would need two UHF
links or 2 phone lines. There are some controller boxes for HF that were
made years ago, but are no
longer on the market, and used ones, if you can get them, have no
replacement parts available for the obsolete
IC's they use, so you don't know how much longer they will continue to
operate.

I am leaning in the direction of building a homebrew DTMF controller.
There are some little DTMF boards
that can be used as building blocks that save some of the design work.
There is no technical reason why a
really nice interface such as you describe couldn't be built, but for
marketing reasons or whatever, there is
nothing like that on the market to my knowledge. Now that Kachina has
fulfilled this need after a fashion, it
keeps other possible controllers off the market due to competition.

The handful of remote HF stations I am familiar with, except for the Kachina
ones, all have one of a kind
solutions that get those stations on the air but are not of much help for
anyone else.

I would be happy to compare notes with anyone else interested in this topic.
I am building a station
out in the country that I currently operate only on weekends and would like
to be able to operate
remotely during the week

I am using an ICOM IC-706 (original) with a Link Comm controller
(http://www.link-comm.com) on a UHF GE Mastr II repeater. The setup seems
to work well. I don't what functions of the radio are actually controllable
via the serial link, but the Link Comm controller implements enough to
actually be able to work HF remotely with control over two VFO's, scanning,
frequency and mode selection, split operation, memory recall etc.
BTW, I use an SGC automatic tuner with a G5RV to give all-band operation via
the remote.

Source record: 54687

If you don't mind using up a few green stamps, International Crystal can get you just about anything. Even more impressive, they seem to know anything in milliseconds. Just give them Heath's old model number (was it a HW-36? I don't remember) and they will know exactly the load capacitance, holder, etc. for the crystal. The big ouch? It'll probably cost $25 by the time you include shipping.

You mean a crystal isn't a crystal? Well, yes. International Crystal is real hung up on the crystal working on the frequency you specify. If you get the wrong characteristics, it's possible the crystal won't oscillate at all, but more likely it will be slightly off frequency. Probably not enough to matter for your Sixer, however. Remember, you will probably adjust it with the trimmer, so unless the crystal is way off, it's not going to matter.

I have no connection to ICM other than as a customer. I always moan when I find out what it will cost, but I like getting exactly what I want with no fooling around.

> of Vackar's original paper.

Dear OM!

The Vackar oscillator has been described in the QST of September 1978, page 15 ("Meet the Remarkable but Little-Known Vackar VFO!" by K6BSU).

In the QST of January 1980, page 19 you can also find an article by W1FB about how to build a Clapp ("A Beginner's 3-Band VFO").

Strange but true, instead of the coil in the Clapp you can put a standard 3.58 MHz ceramic resonator in series with a 150 pF variable capacitor. Those CRs are very stretchable, so you will be able to change the frequency between 3.5 to 3.6 MHz with an even greater stability.

Ask the ARRL to send you a copy of each article. If you cannot get it, send me your address and I will send you the two copies by mail.

Hi,

I would like to obtain a copy of the Spring 2000 issue of QRPp. I
am specifically interested in seeing the construction article on
the St. Louis Pocket Vertical antenna. (This is different from the
St. Louis Vertical.)

Can anyone help me obtain this article in one form or another?
I'll do whatever it takes to get a copy of this article.

Backissues of QRPp are available from NorCal only from 1998 back,
nothing yet for '99 or '00. Thanks for your help,

There are no fundamental differences between any of the various 'names' of oscillators. They all have the same order of frequency stability when working with the same transistor and DC supply. One cannot expect much to happen just by grounding a different node of the simple circuit or having two capacitors in series instead of one,

The various oscillator names do, of course, provide the radio magazines' old wives and authors and technical editors with whole lifetimes of plagiarism, repetitions and regurgitated waffle.

Your experience almost exactly mirrors the results that Consumer
Reports got a few year ago. There turns out to be very little you and
do with normal alkaline batteries.

The rechargable alkalines, however, use a different chemistry and
recharging them works pretty well.

It looks to me like NiMH batteries are the next wave in
rechargability, however. Their price is just starting to come down.

Isn't it true that one of the biggest difference in oscillators is how well isolated the frequency that the oscillator is from undesired effects? For example, one would normally want to make the frequency of oscillation relatively independent from the undesired potentially relatively uncontrolled parasitics in the constituent active and inactive devices.

Purely from a 'theoretical' standpoint, it would be best to choose a design that is relatively independent of the varying parametric effects of the active devices, minimal effect of active device LF noise, and obviously other necessary requirements (e.g. proper gain/phase levels, etc.) Ideally, the frequency determining components are those that are 'planned', and the effects of device parasitics (that are likely dependent
on numerous aspects of the environment (temperature, etc.)) are minimized. Of course, in circuits with stringent requirements, one does need to consider the various parasitic effects, but minimizing the effects is a first order design optimization.

Some oscillator circuit designs might simply let device parasitics strongly affect the frequency of oscillation, or be more susceptable to the LF noise characteristics of the active gain device.

It really doesn't seem like there is any 'magic', other than understanding the design goal, and understanding the various, sometimes subtile, effects of the circuit design.

I am going to provide two design tradeoffs that might make an oscillator work better or worse:

1) It *might* be a good idea to decouple the resonant circuit from the active device. One goal
of the decoupling might be to lessen the effect of device capacitance, and make the side effect of the varying device capacitance less significant than a circuit that provides more intimate coupling between the active device and the PLANNED frequency determining part of the oscillator circuit.

This decouplling is probably one of the biggest differences in oscillator circuit designs.

2) It *might* be a good idea to make sure that the DC bias circuitry doesn't have any unplanned
LF noise effects. Such noise could increase either AM or PM noise in the oscillator output.

There are MANY other design issues, but this comment is meant to show that it is best to create a design with desired effects, and snake oil isn't needed!!!

Message-ID: <3a90a366.18215572@news.mwci.net>
Source record: 54552

I have a pan/tilt assembly in which a CCTV camera was mounted on. It was originally controlled by a special keyboard that I do not have.

There are 2 motors on the assembly. One for pan and the other for tilt.
The information on the motors is: 1=41 2/3
UFB1NO5F41ASN4M
SAIA
Muten Switzerland

A PC board is also mounted on the assembly. Each motor has it's own PBL3774 and PBM3960 ICs. There also appears to be a uP IC that probably received serial commands from the control box.

All I want to do is control the movement of the motors with toggle switches (UP DOWN LEFT RIGHT) for camera control.

Can anyone help me reverse engineer this design?

Randy, WB0VHB

1156. Mitrek antenna cable type?

I am trying to order connectors for a Mitrek that I am modifying, but I don't know what kind of cable it is... I've searched the manuals however I see no reference to a part number or even a description.

What is the official model/name of the white teflon cable inside a Mitrek? Does it have an RG number or equivalent?

Thanks!

It's really too bad that good oscillators are more difficult to design than Reg says, but then many things are. For people really interested in this topic, I highly recommend the treatment in Hayward's _Radio Frequency Design_, now available from the ARRL. It does an excellent job of showing the similarities among the various oscillator types, as well as their differences. It also tells what factors are important in achieving the results you need and how to implement them. Wes has spent a long and successful career designing professional test equipment and commercial RF and microwave ICs. I'm proud to join him as a fellow member of Reg's Old Wives Club.

> one,

There are quite a few differences in the various oscillators other than "what point is grounded." For example the classic Hartley oscillator uses a high-pass network in the feedback path, while the Colpitts uses a low-pass filter. The Clapp is similar to the Colpitts, but uses a bandpass filter for feedback. It can achieve better stability since the large capacitors on either side of the series network swamp any capacitance changes of the active element. But technically a Clapp oscillator can use an inductive divider too.

The simplest way to look at any oscillator is two four-port networks coupled together. One of those four-ports is the amplifier and the other is the feedback network. Meet the Barkhausen and Nyquist criteria and you have an oscillator. Which connections are grounded is unimportant to the analysis (except when "real" components are used - see below).

For example in the Hartley, the high-pass network has a 180 degree phase lead at the resonant frequency while the amplifier has a 180 degree phase lag. The amplifier must have sufficient gain to overcome the losses in the feedback (and actually a little more for the oscillator to start).

Compare this to a Colpitts oscillator where the feedback is a low-pass network which provides a 180 degree phase lag at its resonant frequency with the amplifier providing an additional 180 degree lag. In both cases, the total phase shift is an integral multiple of 360 degrees (0 - Hartley, 1- Colpitts). Now look at resistor-capacitor phase shift oscillators and understand why it takes 3 of each.

As John (JD) wrote, there are many criteria to be met when selecting an oscillator design. The effects of "real" versus "ideal" components must be understood, as well as the

basic differences in circuit topology. Stray capacitance, inductance and transmission line effects can be extremely important at higher frequencies.

But saying that a low-pass network is identical to a high-pass network to a band-pass network sounds mighty strange coming from you.

> The various oscillator names do, of course, provide the
> radio magazines' old wives and authors and technical
> editors with whole lifetimes of plagiarism, repetitions
> and regurgitated waffle.

The names are important only in that they honor the inventor. If you understand the oscillation criteria, and the feedback networks, it is pretty easy to understand almost any oscillator topology.

VFO oscillator circuits came into and went out of fashion like the length of women's skirts. Now we have digital synthesisers.

VFO circuit choice is influenced by the load and output point.

Everybody has his own favourite. My own favourite is an inductor between FET drain and gate with the source tapped into the coil near the drain end. The tuning capacitor is in shunt with the coil. The drain end of the coil is grounded. Oscillator output is taken from the coil tap. I don't know the name of this particular circuit. But it's a good one. Rock stable. I invented it myself but I'm certain a 100 or more people will claim precedence.

Regards, Reg, G4FGQ

IRF630N is a current International Rectifier part. Have a look at the data sheet, available from www.irf.com. Power mosfets used for switching supplies and the like have quite a bit of gate capacitance, and AFAIK get pretty inefficient as RF power amplifiers much above 40 meters. Should make a decent amp on 80 meters. My most current experience is with switching supplies at ~3 - 6 MHz, where choice of FET did indeed affect the efficiency.

Cheers,
Tom

Hi,

Yes, I put something like this together which even rings the
other phone when one is taken off hook. I'll have to scan
the schematic and email it to you (later today).

I built this to connect an Aplio phone to a local workstation
running as an ISP, so I can say that it works up to 33kbps.

If the meter has suffered mechanical shock, the jewels may be cracked or the pivots bent. The pointer may be rubbing against the dial scale or the glass. It may just need a drop of clock oil on the pivots. Finally, some dirt or iron filings may have gotten to where they interfere with movement.

Bearings either too loose or too tight can cause the needle to stick. Particles of dust or whatever is more likely the trouble. Be sure to use non magnetic tools around that thing or be super careful. The magnets are small but very strong.

Low pressure air might be a good starting point to find the trouble.

Hallo..

Ik heb een klein probleempie..

als ik mijn voeding inschakel dan neemt deze een zeer hoge piek af uit het net.
Dit heeft als gevolg dat mijn Automaat van 16 Amp eruit vliegt.

Ik kan dit veranderen door een stop maar dat wil ik niet.

Is er een andere oplossing zodat ik de piek kan verminderen met inschakelen van de voeding.

hij 13,8V en geeft 2x20 amp af sec.

primaire is hij af gezekerd op 10Amp

I have repaired meters with this problem before. Just open it up and be VERY careful with it. Use bright light and magnifying glass. You will probably find some magnetic trash between the poles that interfere with the coil movement. If not this, see if the spring is clear to move OK. I saw a spring once that had somehow wound around itself. The bearings are probably OK.

From: Piotr Balcerzak <bpiotrek@yahoo.com>
Message-ID: <_Djk6.259344$f36.10169654@news20.bellglobal.com>
Source record: 54567

Try MOSFET (BF981, BF961, etc.) at RF input, TDA1574 as mixer
and first IF amp, TDA1576 as IF amp, detector, signal level indicator
and 1578 as stereodecoder (all of them should be very inexpensive).
ICs' descriptions, technical data and application circuits you can find
on http://www.philipssemiconductor.com
If you make good PCB board, you will have decent FM tuner!
(If you add TDA1572, you will have decent AM BCB radio, too.
And SAA1057 or TSA6057 will make your tuner PLL synthesised :))

Hope this helps.

Piotr

Any info on where/how to find this magazine? I'd love to take a look at it.

And I will post periodic updates as to the tuner's progress... :)

Thanks,
Clay

Just from a thinking out loud point of view, you could take any
old junk $15 tube tuner off of ebay and add some modern
refinements. Among those would be a good RF amp stage,
stabilising the osc freq (or adding AFC if its not incorporated),
then spawning off a stereo adaptor type of circuit. No need to
re-invent the wheel, there are many old circuits out there that
have been time proven to be "correct" and the modern refinements
like stereo adaptation were well versed 40 years ago.
Unfortunately, selectivity wasn't a critical topic back then.
Parts would be readily available, etc. for such a project.
I'm not sure what the mission is here apart from simply having a
high-end DIY radio. Its not like re-designing a simple triode
"tube amp" that has some perceived enhanced performance over
modern solid state equipment. In terms of FM reception, anything
made in the era of transistors will pretty well whoop-ass over
anything made with tubes, but from a hobbyist standpoint, a fine
tuner made by hand has its own appeal.
Sounds like an interesting project. I'd recommend checking out
some of the old early 60's gear that had stereo to see if such
circuits could be replicated. Chassis pulls from old consoles are
pretty cheap. A junker off ebay could provide the necessary
components, or itself be a basis for refinements.
Good luck with such a project.

Alex,

For up to 3 amps, use the LM350K. Also, the reply from JW is essentially correct, but - It could be misunderstood. The resistor is in series with the output from the regulator. ... One end of the resistor connects to the regulator output. The other resistor lead goes to the load. The adjust port on the regulator connects to the load end of the resistor. The resistor must also be rated for the current draw and power (1.2 volts X current = watts). Total voltage drop across the circuit will be about 3.5 volts - or more, depending on the load and current.

```
--in--- Regulator --out-- Resistor ----- load

Sorry about the stupid question, I am looking into a CW transmitter that uses tubes. I have done a few other more modern rigs, and would like to try one that uses "valves". I had a question on the power supply. It requires +250V DC for B+ and 6.3 AC for the filaments (I assume) What power supplies available will do that? I have a feeling I can't find this one (power supply) at Radio Shack..

1178. 2.4GHz feed to 2ft (60cms) offset Gregorian dish

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-20 13:03:14 UTC
From: steve@btinternet.com
Message-ID: <3a9265f4.362623@news.btinternet.com>
Source record: 54575
Cross-posted to: rec.radio.amateur.homebrew,uk.radio.amateur

I'm wanting to use a 2ft (60cms) offset Gregorian ex satellite dish for 2.4Ghz. I wonder if anyone has a design for a simple circularly polarised feed?

The true focal length is about 37cms but as its an offset dish it varies from 37cms nearest to 60cms at the furthest point from the focus. My guess is that I should be using a mean value of about 48cms to calculate the f/D - giving a f/D of about 0.8? - hence I should be looking for a feed with a 10db beamwidth of about 70 degrees (3db beamwidth of 40 degrees).

Could the dish be feed with a small helix antenna (8 turns gives about this beamwidth) - I can't find any reference to feeding dishes with yagi (other than a simple dipole and single reflector) so I guess it must be a bad idea for some reason (probably defuse focal point?).

> rechargability, however. Their price is just starting to come down.
==========
Yes ,indeed .....however like Nicads ,when on the shelf ,they gradually loose their charge ,so it is best to keep them on a low ,safe trickle charge ALL the time.

Having quite a number of AA type and slightly larger (type ?) NiCad and NiMH cells I regularly give them a day or so trickle charge and once every half year a full discharge eg to 1 Volt per cell followed by a pulsed charge-and a day of trickle charging . This keeps them in good condition

Not having any experience with re-chargeable alkaline batteries , I would like to know how these behave while on the shelf.
I do know that normal alkaline batteries eg Duracell , have a shelf life of several years.

I'm lost. I don't have a tube manual, and I've searched online and
can't find any help.

What I want to do is fix a design flaw in an old receiver without
hacking the thing up more than necessary.

I can cure the problem without cuttiung things up too bad by using a
nine pin tube (like the 6U8A) but I need a semi-remote or remote
cutoff tetrode sectioon so I can AGC the tetrode.

Anyone know off-hand what might work???

Thanks.

Tom:

Power supplies are among the easiest electronic devices to build and parts are plentiful. The supply you need could be built in many different ways and the Radio Amateurs Hanbook has had such designs for over 50 years.

Back when radios, TV's and other consumer electroic devices used vacuum tubes, it was easy to salvage the transformer, rectifiers, filter caps, etc for ham radio power supplies. It is a little harder now, but it is still not dificult to find such parts.

The 6 volt filament transformer can probably be found at Radio Shack. The 250 VDC will be a little harder, but there was an article in the Jan 2001 issue of Electric Radio Magazine where a supply similar to the one you need was built with 4 filament transformers. It puts out 6, 12, 18 & 24 VAC for filaments and 275 VDC for B+.

A little research will probably give you even more ideas.

Hi Steve,

Go to the W1GHZ site- a quick search will bring up the URL. Paul has an online tutorial for dishes/feeds. The VE4MA/IMU polarizer feed is very efficient but the feed blockage would be quite prohibitive for a 60cM dish as the scalar is large. However, the diagonal feed by N7ART w/ polarizing stubs may be a good solution- the VE1ALQ site details this feed. F/D of 0.7-0.8 is very typical of offset dishes.
You might also want to search a W2IMU feed w/o a scalar- probably also on Paul's site.
Hope this helps.

I agree with Roger for 6.3 V AC transformer. It's not a problem to get one.

For the HV, if the power is not too big, you can try two transformers back
to back:
115 VAC -> any voltage and then any voltage (but the same than
previously) -> 115 VAC (or 230 VAC)

good luck

sometimes just wonder if sharp-cutoff pentode works just as good,
HW-101 has 6AU6 as RF amplifier, and has outstanding intercept point,
while SB-300 with 6BZ6 hasn't, it is badly overloaded on 40m, but this
is probably caused by too low cathode voltage and voltage drop over
grid resistor

The makers of rechargeable alkaline batteries claim a shelf life similar to standard alkalines, and I have no reason to doubt it. I looked into using these cells not long after they came out, with the intended application being to run a GPS unit which drew about 250 mA. It turns out that at that current level, the initial capacity wasn't all that great, and the capacity deteriorated within a few charge cycles to less than a NiCd cell (and much less than a modern NiMH cell). In addition, the internal resistance increases pretty rapidly with the number of recharges. I suppose they've got their uses. But considering the very limited lifetime, very poor performance at even moderate currents, initial expense (including special charger), and the availability of primary alkaline cells at Costco for about 25 cents each, they've never been a solution for me. I keep some primary alkalines for emergency use, and use NiMH cells whenever I know in advance I'll be using them.

Thanks all.

A 6AZ8 is about the only tube I don't have laying around!

I want a remote cutoff tube because I need to AGC it. It is after the selectivity, so overload is not an issue.

Thanks all.

Source record: 54591

I've fixed a few and ruined a few, so take that in consideration
if you read this ramble.

Except in the case of a dropped multimeter, when anything can
happen, the problem is nearly always one of the two following
cases:

1. small (almost microscopic) piece of magnetic material lodged
between a pole piece and the armature. A strong light, good
magnification and a steady hand can ofter locate and remove (or
more likely, reposition the material so it now longer interferes). This
may not be ethical, but, hey!, it works. Any attempts to blow it out
with compressed air or washing out with a fluid, will nearly always
finish the meter for good. I have examples.

2. glue is sometimes used to anchor the armature shaft pieces to the moving
coil, even on some very expensive instruments. Some older instruments were
found with the glue cracked and the shaft/moving coil misaligned. The coil
will then "drag" on a pole piece somewhere in the needle's arc of travel.
Novices have repaired these occasionally with a part of a drop of super glue
on the end of a sharp, round toothpick. The trick, however, is to have
propped
the coil and shaft into proper alignment with wedges of paper or ??? before
the glue is applied. It is useful to know that getting the super glue on
anything
other than the intended spot also results in an expensive failure (or
inability
to let go of the meter).

Some watchmakers have a little experience with D'arsonval meter movement
repair, but my experience is that unless you do it yourself, the cost of
instrument
repair by a professional (if you can find one) is more expensive than the
meter
itself. (worth it if the meter must be the "original", and new is out of the
question)

A good, steady man, with no experience has maybe a 50-50 chance of success.
Don't call me if it doesn't work.

>several years.

The rechargable alkalines don't discharge on the shelf at all, so they
are great for emergency stuff you put away and expect to be able to
use when you need it. OTOH, Ray-O-Vac claims that after about 25
charge/discharge cycles they will be down in capacity to approx the
same as a NiCad of the same size.

I found they would not work in my digital camera if I wanted to use
the flash; the voltage pulled down and I lost the image. So I guess
they are not good for high load applications.

I have switched over to them almost exculsively and have been
generally happy so far, although I did have one AA which was
completely dead (and not chargable) out of the box.

I probably have 30 of them around here in one device or another, from
AAs in a VOM to Ds in flashlights.

I assume that by "federal" you are referring to something belonging to
the US government.

Fortunately for (at least the rest of the world), the Central Bureau
of the IERS is in Paris, thus, the leap second issue is independent of
which party happens to be in charge in Washington DC :-).

Source record: 54594

Tom,

Assuming you'll need to build your own, it's not as hard to get these voltages as you might think. The "obvious" solution is to find a single suitable transformer, say 500 VCT and 6.3 V, but this may not be easy. Two other solutions also come to mind: (1) get a 240:120 isolation transformer (NOT autotransformer) and wire it backwards, feeding the 240V winding into a bridge rectifier. The Triad N-68X is one that I've used and you can find them pretty easily. (2) get a normal 1:1 isolation transformer and have the secondary drive a voltage doubler. In either case, using solid state rectifiers you'll end up with closer to 300V than 250V, but your tubes won't mind. For the tube heaters use a separate filament transformer (Radio Shack has 'em). I like to use 12.6 VCT transformers so I can run either 6V or 12V tubes.

In addition I'd suggest that you come and join the glowbugs mailing list for ham tube homebrewing. Here's the info from the rec.radio FAQ:

For homebuilding transmitters and receivers using tube technology,
there is the Glowbugs e-list; send an email to:
majordomo@piobaire.mines.uidaho.edu and only write:
subscribe glowbugs <your@address.here>

BTW, what lineup are you planning to use?

I plan to put a 144 MHz transceiver, feeding a standard coax cable (RG 213),
near my LAN (Ethernet 100 base T).

Does anybody has an idea of the minimum distance between the radio cable and
the LAN cable to avoid interferences.
The power of the 2m transmitter is about 20 W.

Thank you for your answer.

Correct! And on no account place any metal tools near the movement, the
magnetic field will be permanently affected and consequently the
linearity.

On NO account use oil of any sort to "oil" the movement.

The rest of what's written I'd agree with.

Message-ID: <7LTk6.956$Gv.4735@news.inreach.com>
Source record: 54498
Cross-posted to: rec.radio.amateur.dx,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,sci.electronics.design

I apologize for cross-posting, but I'm getting a little desparate.

I need a source for 4.332MHz and/or 8.664MHz (or 17.328MHz) crystals for an important project I'm working on. So far, I've found only one source (Thanks Francine!), but the prudent man never only has one source for a part. This is especially true when that source might have trouble delivering the quantity desired.

So, if you know a place or places that might have these specific crystal values, respond here or send me an email at cautery@montacnospam.com. Note: be sure to remove the "nospam" from the domain name.

I really need y'alls help here!

Thank in advance,
Clay

Hi Dale,

If you need a special expensive meter repaired or rebuilt, there's a place in Livermore, CA. that does it... but it's not cheap by any means. If there's a way to replace the meter cheaper than say $150 you'd be better off going that way.

I had some real power meter movement from a Hydro Plant I serviced that were 1950's vintage GE's. They were able to repair and calibrate the movements for about $300 each. When your stuck for an exact fit, you've got to play the game. If you need to play that game, drop me an Email and I'll forward the name of that Company back to you. I have it at home in my address book.

Hi Shawn,

You don't want to have to order that cable new... it's really costly. The best way to find it is to call a two-way radio shop and ask if they have any used or new-old-stock Motorola 800/900MHz antenna kits with that coax. I see the stuff at the ham flea markets being sold by surplus two-way dealers. It's just teflon coax similar to RG-400, RG-393 or RG-404.

You can also call some duplexer mfgrs and ask about it.... Belden has an on line wire web site (that's a pain to use).

Otherwise you should get on the phone or go to the ham flea markets...

Hi Tom,

For an HF remote, there are a few controllers that work. One thought are the original ACC brand controllers which support the kenwood stream (not the Icom). The RC-850, RC-85 and original Shackmaster did a pretty good job as remote base controllers. You will find out that ACC sold out to Link and a technical type in your group will be required to brush up on any use ACC controller you buy. Link has been more than generous about supplying ACC information and limited upgrades/parts.

The ACC Shack Master was a very popular stand alone HF radio controller.

Pacific Reseach is making a nice controller, I'm not sure if they yet support the HF radio setups, but they do remotes on higher bands via commercial radio retrofits that work pretty well. They do have a web site that's pretty informative. Hold on to your pocket book...

If you want to pull out your hair, Link Com has a series of controllers that probably interface with some HF brand radios, but I must say their software is every quirky and not user friendly. I also have some issues with their hardware layouts, but other people don't seem to mind their onboard telco patch approach. They do seem to offer up a few different controllers via their web page. I will say that Alan and Steve at Link are pretty nice people to deal with over the phone. Link seems to be the current bells and whistle leader in the controller department. They promise many features, but the software often has to catch up to the promises through "upgrades and revisions."... many of them.

Scom makes the 7K controller which interfaces to the Hall Electronics (Kenwood Remote). You might check the Hall Electronics site (same people who make the "poor mans voter card") to see what the current capacity of their remote interface is. S-Com also has a web site that has just moved to another server. You might have to search a bit for it.

Cat controllers make "the poor mans bells and whistle controller." If you like things that go bump in the night, have a look at their web site. I wans't impressed with their quirky software, but many seem happy with the controllers and they do work. Remote base software might not be something they include in their controllers.

****

Your thoughts about using surplus Motorola two-way equipment are good, other brands with good receiver front ends are also a go. Dont' overlook trusted types of GE and smilar rigs.

You should turn the HF Radios power level down as low as practical, else you'll have rf floating all over the place. I run my remote at 25 watts and it talks up a storm. Try to avoid running astron power supplies on hill tops... they seem to fail much more often than surplus commercial units.

good luck on your project...
cheers

I had several receivers where agc were applied to sharp cutoff valve,
so I find it difficult to see much problem in doing so. One such was
Kenwood TS-500 where 6U8 (or 6BL8) was used in the IF. When AGC time
constant was optimized it performed very well.

One suggestion is to feed AGC over a divider, but I have no experience
that it might be needed other than for mixer type 6BE6 as used for
Drake 2-A and 2-B

Hi there!

There is a complete Society dealing with crystal sets in St. Louis. They
publish such books and their regular "The Xtal Society Newsletter".
Their second name is "Midnight Science". Nice people. You can find them
at www.midnightscience.com

Best wishes from Bozidar 9A2HL

By Presidential Executive Order, November, 2000:

"In heavily non-Republican precincts, leap seconds shall be repeatedly
locally
inserted at 18:59:60 to assure fairness to horologically-challenged voters
who
are otherwise unable to be transported to the polls before they unjustly
close.
In reparation to dead voters and those who have suffered vote oppression in
centuries past, such voters shall receive triple vote score if they indicate
the appropriate voting intention to the transport driver, whether or not
they
choose to ride. A new Cabinet-level advisory position, chairing the
Department
of Synchronization, shall be chartered to help citizens and others in those
precincts interact with the temporal world; in no case shall an event
legally
occur without Department of Synchronization approval to prevent conflict
with
other lawfully permitted moments."

Be glad the French do it.

Hi guys !
I am really interested to operate my HF radio in a field, but I have no idea what stuff I need to have for this. As I know, I have to use some "deep charge" battery like YUASA or EXCIDE instead of regular car battery.
That's it - I don't know anything else ...

Environment: Field or small hill, FT1000MP, 50-100W SSB-CW, medium activity, about one day operation ...

What kind-type-model of battery I do need?
How many Amp-Hours?
Do I need to install fuses in DC cord? How many of them?
How I can recharge the batteries?
Any suggestions about antenna type - multiband dipole, delta, vertical ?

I will really appreciate everything - links, books, magazines, personal stories, dealership names&locations ....

From: N2PKT <wireless@geocities.com>
Message-ID: <974e2jgsm1@bob.news.rcn.net>
Source record: 54522

I recently built a "Fox Hole" radio. Suprisingly, with a little trial and error, I started to receive a local AM broadcast
on it. Understanding that these type of basic radio sets do not bring in room filling sounds, is it possible to make the
signal strength (volume) louder? I attempted to place a .001uF cap between the crystal earphone, but the results were
the same, just a very low signal. Was my placement incorrect? This was a great homebrew to make, It's simplicity and
history made the project all the more interesting. I am in the process of looking for the right razor blade with a good
amount of "rust" for a diode. That may help, but in the meantime, any hints on "beefing up" the volume would be helpful.
Thanks you for reading this post.

> What kind-type-model of battery I do need?

Really big to meet your wishes (see below). As you say, deep
discharge rated. Brands are less important. I would not buy a battery
that is only rated for "cranking" and "reserve" amps. I ran across
this for some so called deep discharge batteries. I feel that if they
won't specify the A/H at a given discharge rate, there is a (not so
good) reason.

> How many Amp-Hours?

Check you radio manual for radio current draw on receive and
transmit.
Number of receive hours times (x) amps = xx
Number of transmit hours times (x) amps = xx
---
add, then multiply by 1.25

This is the amp-hour rating which will about suit you needs. Note
that most battery A/H specs are for a 20 hour rate. Shorter times
(higher discharge rates) reduce the effective capacity. The 1.25
factor is an attempt to compensate for this and to avoid completely
discharging the battery during use period (hard on bat life + radio
may not work well on 11 volts or so).

> Do I need to install fuses in DC cord? How many of them?

Fuse both the + and - leads from the battery as close as possible to
the battery. Use heavy duty fuses and large wire to minimize voltage
drop. For a SHORT run using your rig, I would use #10 or larger.

> How I can recharge the batteries?

A battery charger :) Seriously, for a battery of the size you are
requiring, a genset and charger would be best. ...Of course, if you

have the generator, you don't need a battery. A very large solar cell array / charger if you have lots of sunny days between sessions. It could be done with a car/truck, but would take a while and could be dangerous to the vehicle systems if not done just right!!!! Beware of this.

> Any suggestions about antenna type - multiband dipole, delta, vertical ?

This depends entirely on what bands you wish to use and what will be available to mount the antenna. Generally speaking, and given there would be something to hang it from, I would go with dipoles for the desired bands. A vertical would be practical only if it is the type using a "counterpoise" rather than radials. Sufficient radials for a "conventional" vertical, for this mode of operation is not practical.

A (fishing) spinning rig, slingshot with reel/line, or small bow/arrow w/reel line, and some nylon cord can be very useful to hang dipoles. I prefer the bow/arrow for best range and control. Have weighted, blunt tip arrow with hole drilled in nock? (rear) to tie ~17# fishing line. Use that to pull up 1/16" or 1/8" nylon.

Thank you for the kind words, Mr. Rochat. As it turns out, I *don't* have a great deal of free time, but I do have a patient and understanding wife. ;)

Some of the images you referenced are here:

http://www.azstarnet.com/~pfriedr/transistor/gaudion.gif
http://www.azstarnet.com/~pfriedr/transistor/jtball1.jpg
http://www.azstarnet.com/~pfriedr/transistor/whisk-w.gif
http://www.azstarnet.com/~pfriedr/transistor/xsist2-w.gif
http://www.azstarnet.com/~pfriedr/transistor/xsist4-w.gif

As I may or may not have mentioned earlier, I've begun the slow and tiresome process of putting together a new book, that will feature these and similar projects.

BTW, if anyone has has any old radio or experimenters magazines that contain references to the actual construction of point contact devices, I'd be very interested in photocopies, and more than happy to pay for them. Specific information about construction is rather hard to find.

I'm also looking for any period articles on the work of C.G. Smith or J. Lilienfeld (1920's) They were both playing with "transistors". Metal oxides were being experimented with as well.

If you're actually using a "crystal" headphone, try shunting it with a 10k resistor. This helps provide a dc return path, and may improve the sound.

Hello--
Adding a capacitor in series with the earphone probably won't help increase the volume. You'll need to add a stage or two of amplification.

IIRC, the original foxhole radio design relied on a blue-coated razor blade. The bluing process used a selenium compound, and hence a lead pencil point pressing on the blue coating formed a crude point-contact diode.

Try substituting a more-modern germanium diode (probably still available from Radio Shack) and see whether the volume increases-- a diode is generally a more-efficient rectifier than a razor blade, but it's fun to experiment with different detector materials. Try various kinds of oxidized metals (e.g., copper).

While it makes sense to fuse both the + and - leads when operating rigs directly from the build in car battery, in case the heavy wire between the car frame and the - pole of battery is broken or disconnected. In this case the starter current would flow from the permanently installed radio frame (or antenna ground plane) through the negative radio power supply wire to the battery, causing a lot of damage.

If the radio is operated from a dedicated deep discharge battery, which is separate from the electric system in the car, I do not see any reason for putting a fuse on the negative pole, since it only increases the loop resistance. The fuse installed close to the positive pole of the battery should be enough to protect the wires in case of failures in the cabling between the battery and the radio. The internal fuse in the radio should protect against failures _inside_ the radio.

1241. L/C ratio

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-24 03:45:21 UTC
From: Bill Meacham <NOSPAMexray@coqui.net>
Message-ID: <3A972E51.69B51A8@coqui.net>
Source record: 54538

I'm looking for suggestions to try on resolving a problem with an
old radio.
Radio is a Setchell-Carlson 407 and tunes 4 bands:
150-400kc
550-1900kc
4.0-11 Mc
11-36 Mc
The tuning cap is a standard 365pf looking one, same on all bands,
although given the tuning range on BCB, it must be slightly
different (less?). The problem is on the top band...the
oscillator cuts out below about 15 Mcs. The coil for that band is
only 3 turns of hookup wire on a cardboard form of about 1" and I
suspect that it probably never was very stable since that looks
awful small to be tuning all the way down to 11.455 kc. It works
well right on up to 36 Mcs.
I can fiddle with the components and move the band up the dial and
receive those freqs, but still the bottom end of the range is
dead. The tuning cap is not shorting because it works fine on the
other bands. Also the osc has been proven to be the culprit by
listening to the LO on a separate radio. There is no trimmer on
the coil. Tube is a 6A8.
Is there something I can do to this osc circuit, like maybe
improving the Q by using a more suitable wire on the coil? I'd
like to keep it where it matches the dial calibration.
Any suggestions?

But it worked when new, didn't it? What has changed? Could the tube be weak, or some other component like an emitter whoops, I mean cathode bypass capacitor be aged, so as to decrease the gain?

How do you expect to get such attenuations when cable leakage is much
more than that above audio frequencies.

Probably. There are a number of crystalline modes, and a
crystal has to be cut in a special way to encourage
oscillation on any harmonic.

10XJ are so large as to lack any technology in crystal
cutting, being just a lump of quartz.

How's about running your oscillator on its fundamental, and
then using a multiplier stage as in the osc-mult-PA style of TX?

10XJ is about the same size as FT-243, but English
If FT243 or 241 works it is no reason for 10XJ not working

I'm guessing that it worked when new. The osc circuit was a bit
re-vamped (factory change) from what is shown on the schematic.
I've juggled all the combinations of component values around the
tube to see if I could do any better, no cigar. The tube socket
has been replaced and of course every possible substitute tube in
the shack has been tried. The only option left seems to be the
actual coil form and windings as I don't feel too good about
cotton-covered hookup wire for coil windings in this 'iffy'
application.

Larry
Just an afterthot. If your PS uses pass transistors, you can
add short circuit protection with another transistor across
one of the pass transistor equalizing resistors.
If and when the SCR fires or output shorted, drive is removed
from the pass transistors and the voltage momentarily goes to
near zero, cycling til the overvoltage or short is removed.
No fuse needed. No damage to components.
See any of PS or 3-terminal regulator application notes
for circuit.
I usually use a 3-terminal regulator and pass transistors
in my PSs. PNPs and a positive LM 317/350 or NPNs and
a negative LM337/LM???.
The short circuit protection transistor is same polarity
as the pass transistors...

The crystal may be low in activity (due to high ESR - Equivalent Series Resistance) but have sufficient activity to allow it to oscillate ok on fundamental with the loop gain of your oscillator.

Crystals can have low activity due to poor surface quality (lapping process), surface contaminates, non parallel major surfaces etc. Crystals for use on an overtone are usually lapped or polished to a finer surface finish than fundamental crystals. Also the two major surfaces need to be parallel to a greater degree. Fundamental crystals may be slightly convex so as to decouple the edges of the crystal. Depends on thickness / diameter ratio.

10XJ holders dont offer a hermetic seal. Over time particles can get in and contaminate the surface of the quartz plate as can the chemicals used in the manufacture of the plastic 10XJ holder. Many years old now.

So, you could do two things to try to get it working. 1. remove the quartz crystal from the 10XJ holder and soak it in Isopropyl (orderable from Boots). Then hold the quartz plate by the edges. Dont touch the major surfaces of the crystal with your fingers directly. Use a piece of silk (a hanky maybe) soaked in Isopropyl between your fingers and gently scrub the plate. Then soak it again. Dry the crystal with a hair dryer. Hold the crystal with tweezers. Also wash the two metal plates which sandwich the crystal.

If that doesn't work for you the only other approach is to increase the loop gain of your oscillator at the desired overtone frequency so as to overcome the resistance of the crystal.

Fundamental crystals marked with a fundamental frequency and used on an overtone never oscillate at the exact multiple of the fundamental. Can be many kHz off. Better to use your fundamental crystal on its fundamental and multiply up.

If you need to use a crystal on an overtone, best to use one calibrated and marked with its overtone frequency.

1256. Free DDS board (for postage).

I have been selling off the remaining partial kits of Novatech Instruments'
DDS3m module kit,

http://www.novatech-instr.com/dds3offer/dds3pdf.pdf

and

http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=1216221284

but even after the kits are gone, we will still have almost 100 boards.
That's what happens when you buy 1000s at a time.

I hate to throw these in the trash, so for the cost of self-addressed
return legal size envelope with $0.55 postage on it, I will mail out
boards to anyone wishing one. No need to email-- just send your
envelope to:

Novatech Instruments, Inc.
attn: Steve Swift
P.O. Box 55997
Seattle, WA 98155-0997

If you want more than one, send me email and I will figure the postage
for you. This also applies if you are overseas or in Canada.

I will repost a message when the pile runs low. I doubt that I will get
100 letters.

Please look at the documentation, which has the schematic and parts list
in it. Perhaps you can use the board for something useful.

We will be cleaning out all our "factory seconds" in the next few weeks, so
if you need something in "older" DDS, send me email. I might have it.

Thanks,

Steve.

Many thanks for the feedback - I just happen to have half a pint of Isopropyl alcohol in the garage (dedicated amateur in many fields of study!) I'll try cleaning the crystal - when you spoke of age, I realized to my horror that it had been in my junk box at least 21 years and was manufactured some 18 years before that!

I wanted to run the crystal on the 3rd overtone in the belief that the output would be significantly cleaner than using a tripler (I built a push pull version yesterday, but it doesn't work particularly well, but thats another thread). I hadn't realized however that the 3rd overtone might not be 3x the fundamental, if it will run at 3rd overtone, I'd better check where.

One additional piece. If indeed these are very similar to FT-243s, the
ensure the spring(s) have adequate tension to place proper pressure on the
plates that contact the crystal itself.

Such attenuators do exist. I have in the shack a 0-100 dB attenuator in 1 dB steps. It was manufactured by Pascall, UK, about 5 years back. I forget the price but it was quite expensive. Don't know whether the firm still exists. Built into a solid die-cast aluminium-alloy box.

Cable leakage does not increase with frequency - it decreases. Worst of all at DC and audio frequencies. Leakage occurs mostly at connectors. Use threaded types, not simple plug and socket. Impedance mismatch at connectors is no problem with attenuation measurements.

I have made measurements up to 160 dB at up to 5 MHz by comparison with variable attenuators. A 10 watt signal generator is needed. Without any extraordinary precautions it is possible to make measurements with an uncertainty of a few tenths of a decibel at 100 dB.

I have also made measurements with a precision of 0.001 decibels at frequencies up to 10 MHz. Such measurements are necessary to determining the loss vs temperature coefficients of components and systems when it is possible to vary the temperature only a few degrees C. A high precision is also needed when calibrating field attenuators against laboratory standards.

I guess that it must be quite expensive if you really get such
accuracy as you later claim, even in a controlled constant
temperature.

I also suspect that the VHF/UHF performance is not that spectacular
and since the original poster did not specify the required frequency
range, I originally asked about it.

>Cable leakage does not increase with frequency - it decreases.

DC and audio circuits generally have a much higher impedance levels
than 50 or 75 ohms used in RF circuits, so the capacitive coupling is
a much worse problem. At very low frequencies the coaxial cable does
not work properly as a transmission line, thus the isolation is not
very good. However, due to losses at very high frequencies, the shield
no longer act as a perfect conductor and you can get different
currents flowing on the inside and outside of the shield.

>I have also made measurements with a precision of 0.001 decibels at
>frequencies up to 10 MHz.

I guess that must be the readout resolution in some comparative
measurements but not an actual precision. A 0.001 dB voltage ratio is
115 ppm (0.015 %), so I wonder how this accuracy could be maintained,
especially if some real power levels are involved heating the
attenuator.

Absolute accuracy should not be confused with precision.

To measure attenuation within "a few tenths of a dB" (at any attenuation level) entails detecting a difference between two voltages which are a few percent different from each other. This is an easy job for any voltmeter. Errors are not due to the comparing voltmeter but to the measuring components, cables, connectors and layout.

Accuracy entails comparison with a local standard. There will be uncertainty in the local standard in addition to errors introduced during the comparison process. There will also be uncertainties introduced at each calibration level up to the International standard.

Precision is related only to local effects such as signal to noise ratios. It is relatively easy to detect a difference of 10 microvolts between two voltages of about 1 volt each. This corresponds to a precision better than +/- 0.0001 dB

Message-ID: <gp6i9tcvmvbj1ppa9uvj63sm7mnj2mjk2a@4ax.com>
Source record: 54462

Im thinking about building an hf amp using the 4-1000. A couple of questions. I believe B&W used to make a complete band switching tank ckt complete with switch and coils. I dont think they do any more, at least its not listed on there site but they do list a tank coil without a switch. Any ideas where i can find a complete tank ckt for this tube. Before I get flamed...I know I could wind one but dont want to unless I have to!!! Had some bad experiances winding them when I was in the Air Force years ago. Also is there any web site that has a schematic for this amp. Any help would be great.
Thanks in advance,
Bill Russell

My other post was somewhat lacking...H.P. makes several good 50 Ohm step attenuators. I have both a 0-10 dB (1 dB steps) and a 0-100dB (10 dB steps), both rated to 500 MHz....0.5 watts....accuracy acceptable for home use. We calibrate/check our at work H.P attenuators every six months. They ain't cheap...approx. $350.00 ea. new, but can often be found on the surplus market for $25 to $50.

B&W used to make the 850 and 852 tank inductors, which included
a heavy-duty bandswitch. I forget which plate impedances these two
were designed for, but I'm sure others in the group will remember.
These come up for auction fairly regularly on ebay. I have also seen
them occasionally on rec.radio.swap. Plan to shell out at least 50
bucks, if memory serves. These are not made any more and they
fetch a pretty good price on ebay.
73, David K3KY
P.S. I think you want the B&W 850. I prefer to wind my own. Why
pay 50. for one when you can spend hundreds of dollars in NRE
designing and fabricating your own? :o)

Hi Paul,

Precision, Resolution. These can be the same thing or different;
however neither are a statement of accuracy.

When my old Drake TR-7 VFO gets buggy, I might note some one at
47.1652 MHz and smile at the precision of that reading, and yet it is
off by 40 MHz (an errant 4 is showing). Lots of precision, lots of
error.

However, as your question lies dormant:
> I wonder how this accuracy could be maintained,
>especially if some real power levels are involved heating the
>attenuator.
which is a concern shared by any metrologist. The load is the
defining point of a power measurement. The load must be known and
with power applied - it changes.

The first, and simplest, solution is to over engineer the load's
ability to "DISSIPATE" energy. (sorry to scream in your ear, but
others here needed to hear that) That would suggest using a 100W
continuous service Dummy Load to measure 10W period limited power
measurements. Or simply measure the load under the power applied.

Attenuators, on the other hand, are not 100W and few are 10W devices.
Most are on the order of 0.1-5W. So, I presume you wonder how to get
one of these into the signal path of a 100W rig? You use a
directional coupler to tap a portion of the power (and you need to
know the portion, but accurate determinations are fairly simple) and

feed that tap through the attenuator and add the coupling loss (or that portion) to make a total.

In short, you have a 100W Source, a 100W Load, a 20 dB Directional coupler, a variable attenuator, an attenuator Load (how many miss this one?) and a detector. You can now read applied power at a 1W level instead of the 100W level. And you can measure the variation from that level with reference to your 100W reading to the resolution of the detector. Resolution or precision could run quite high. A measurements of change would also find high "relative" accuracy.

Relative accuracy means you do not need to know where you are, or where you started in absolute terms, merely how far apart they are. There is an interesting implication here in this subject. As we are interested in attenuation, any measurement of an attenuator is both "relatively" and "absolutely" accurate. This is one of Gary Peach's link pins to the absolute measure of received power.

A typical circuit for using the 4-1000 in grounded grid is given in July 1963 QST. This article recommends the B&W 850-A tank circuit, although I have used the 852 myself (admittedly with a lower plate voltage).

1271. PC sound card specs

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-25 21:53:34 UTC
From: "Dave Cook", com
Message-ID: <y9fm6.473453$U46.14111789@news1.sttls1.wa.home.com>
Source record: 54468

I was thinking about hooking my rig to my PC soundcard, but can't find any spec's on the soundcard's I/O characteristics. It, of course, a "SoundBlaster" compatible, but even the Creative Labs tech info doesn't get down to the nuts and bolts. Naturally, my rig is thoroughly spec'ed out - I can choose from the 8 ohm speaker output or a line-out output. I'm assuming the output from the soundcard is 8 ohms. Does anyone have any info on the aux and mic inputs?

BTW, I haven't been subscribing to QST for a while. I'm sure there have been plenty of articles on xcvr<->PC hookups.

There isn't much in the way of specs for the sound cards. Everybody does it a little different. That's really not much of a problem though because there is no need to match impedances - just get the levels correct. Generally, the speaker output of your receiver will drive the line input of the sound card directly. If you have "hum" or RFI problems you may want to add a 1:1 isolation transformer. The line output of a sound card can be reduced by a 100:1 resistor attenuator to get down to a suitable level for the transmitter's mike input. Check out http://www.sedan.org/sedanmap.htm for details on interfacing to a variety of different rigs.

The ones that I have and the ones at work all have BNC type connectors. I have not noticed any problems associated with their use, but our high end is 400 MHz. The only problems we have experienced is a tendency for the locking nut to loosen if Gorilla Grip repeatedly uses the attenuators.

And why would you think that any self-respecting ham who is into homebrewing would be interested in amplifiers that are obviously ILLEGAL CB AMPLIFIERS?

Sweep tubes in one no less!!!!! 2-811s driving a 3-500z! You gotta be kidding GOOD BUDDY!!!

Put it out in the trash after whacking it several times with a sledge hammer!

Wouldn't do just that . Seems to be good equipment to convert to a proper
ham bands RF power amplifier .
After doing that it no longer is illegal equipment.....think about it .

I have to disagree. 1) He is a ham. 2) A ham can legally use these. 3) Yes, they were built for 11mtrs, but no one screams when an 11 mtr rig is converted to ham and extra power output is obtained.

From: "J.F. FOURCADIER" <jf.fourcadier@wanadoo.fr_NOSPAM>
Message-ID: <97egefkhv1@wanadoo.fr>
Source record: 54403

Hello !

With some friends I build presently an ATV repeater. The transmitter is designed for the 23 cm band and the output power is about 15 W.
To cover the right area I need an horizontal polarized antenna with an omnidirectional diagram. A gain of about 8 to 10 dB will be highly welcome.

Any idea or tried design ? stacked halo or big wheel or something equivalent ?

Thank you for your help

The most common step attenuators on the hobby market are the HP355C
(0-12dB in 1dB steps) and HP355D (0-120dB in 10dB steps). They are rated
to 1GHz and normally have BNC connectors.

Higher frequency attenuators such as the HP8494/HP8495 come with N, SMA,
or even APC7 connectors.

I have an old ZEOS Notebook 386 that developed dead batteries when I did not keep them on trickle charge. I carefully cut one of the 2 open and found that the batteries were standard 1700 mah cells that can be be obtained from various nicad sources and soldered together. I can sometimes restore the batteries if not hard shorted by zapping them, but zapped batteries never perform well after zapping, and must be kept on constant trickle charge as you can see from my webpage at http://www.ultimatecharger.com

Agree with you Tom ,but this is a Homebrew NG and homebrewers enjoy making
something good /clean from equipment not necessarily designed for ham
service .
I would find it a challenge to modify this type of amps for ham use.

Odds are you'd never want that crap on a ham band.

CB amps are almost never "designed" with any consideration
given to having a clean signal. As a matter of fact, it is almost
always the opposite.

Tom

I need two pieces each of Amphenol Series 26 24-pin mating connectors to
repair plug-ins for an old HP Spectrum Analyzer. the part numbers are
26-4101-24P and 26-4501-24S. Chances are that I could use parts with
some
variation in the middle number (4x01?) provided that they are mating
pairs of
Amphenol Series 26 connectors. I will appreciate any leads you might
furnish.
Please copy to my e-mail address which is <mycall at arrl dot net>

But even hams cannot offer amplifiers that cover 26-34Mhz for sale in the US,
under FCC regulations part 47 section 2.815. There are exceptions for home
brew equipment offered by one ham to another, but these units do not qualify.

yes by all means read the fcc rules on sales of amps for this freq
range. you will find max amp gain etc. its clear that a large number of
people dont own or have not read part 97. as they said in the movie
"beetlejuice" its in the manual READ IT!

TV and Radio Tower Pictures!

Ever wondered where the television and radio signals you receive are generated? Our site shows you original pictures from the transmitter towers on locations in The Netherlands, Germany, Belgium and the United Kingdom. For many sites a photograph of the antenna tower and its surroundings and a detailed close-up of the aerial system is provided.

In all honesty, you will probably never find a service manual for that piece
of equipment. The manufacturer doesn't want the public to have them. I'm
going through the crap with APC. Good luck.

1312. Frequency synthesis receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-28 15:31:45 UTC
From: j.l.gomez-dans@sheffield.ac.uk
Message-ID: <8766hu3jtq.fsf@sheffield.ac.uk>

Hi!
I have been playing with the idea above for quite some time, basically, a SW receiver made out of ICs. In principle, I have sussed out the demodulation and and amplification bits (it's been quite a while, and can't remember any part numbers), but there are still a couple of things missing. I have had some joy with some frequency synthesis ICs (the specs look OK), but at this point in time, all I have is just some schematics that aren't pinned down or anything. Besides, I could do with some extra information on the whole thing.

As you can see, I am trying to be very general here, but I guess that my question is whether anyone knows of some design implementations of a microcontroller-based receiver that uses frequency synthesis. I have made som progress on a BCD FS chip run by a PIC.

At any rate, any hints, directions and the such shall be much welcomed1 Thanks in advance,
Josï¿½

1313. Air Variable Capacitor Question?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-02-28 16:05:21 UTC
From: Ron H <blahblah@mn.mediaone.net>

What is the equation to relate the spacing of the plates of an air variable capacitor to the breakdown voltage? OR Is there a look-up table somewhere that might list this info for the common spacings? You know, 1/8" = 3000 Volts etc.

Thanks
Ron H.

Dave, I just went through the frustration of trying to wire up the
13-pin DIN for PSK-31 on my TS-450S. After I got it working, I posted
a request for hints. The two best responses I received were:

1. On the back side of the connector, cut off all of the pins you are
not going to use.

2. Go to Radio Shack and buy a female RS-232 connector kit with loose
contacts. Terminate your wires in the female contacts and then just
slide them on to the pins on the back side of the connector and touch
them with an iron and a dab of solder.

If I had to do it again, I'd probably use both suggestions.

Good luck,
Ed - N5KZW

1315. Need for specs of CEPE oscillator STP1671A

I have an Oven Controlled Crystal Oscillator CEPE STP1671A freq. 16.384 MHz.
The frequency is just right for my syntheziser, but unfortunately no specs
available. The size is about with double cigarette box dimensions and it has
5 pins (1 connected to case). Internet search gave no results.
Does someone know the component or company's CEPE current name.

I've seen that data somewhere ... I think it's in "Reference data for Radio Engineers" or something like that. There are separate charts for spacing between round balls, sharp points and flat surfaces.

Ok OK But from what I know about Ion clouds and discharges, I thought that the 30Kv/cm only applies to point discharges! The air variable Caps are parallel planes with some edge effects and I thought there was a different formula! Also, I don't think it's strictly linear! Can I use the 30Kv/cm and divide by say 10 to conclude that a 1 mm gap is good to something less than 3Kv? ALSO! What about real world equipment where the pressure is NEVER 1 Atm or things like humidity vary al over the place? What I was looking for was the formula used to label air variable caps for general application and something tells me I can't just use the 30Kv/cm rule!

How about a rule of thumb voltage/spacing from the ARRL Handbook ? This
is for a transmitter plate tank capacitor.

Spacing (in) Peak Voltage

.015 1000
.03 2000
.07 3000
.125 4500
.15 6000
.25 9000
.35 11000
.50 13000

Hi Bill.

I'm having a similar problem with my old National NC-88 receiver. On the highest band (~14 to 40 MHz) the LO cuts out below 15 MHz and also has problems on the high end.
I, too, replaced the LO tube (a 6C4 triode) with no effect and then suspected the L/C assembly. I am still experimenting.

One thing did improve the LO coverage. I replaced a 220pf silver-mica cap in the grid feedback circuit coupled to the coil. The LO now seems to work down to 14 MHz, but its output level as observed on a 'scope is still much less than on the other bands.

My radio has another mica cap -- 1000pf in the same rectangular style with colored dots --that connects the plate to the coil. I plan to replace that next, assuming that there is some ageing effect going on with these caps at high-frequencies.

If none of that works, I will open up the feed back connection and check out the circuit as a plain RF amplifier. Maybe that will reveal something. It is hard to believe that the coils change much with age. The inductance seems to be reasonably stable because I had no trouble aligning the LO to the dial. In my case, the coils seem very well made and sealed up with beeswax. Might be a low Q problem though.

Good luck with your radio; I'll let you know if I have a breakthrough.

I monkeyed and monkeyed and nothing worked, but guess what...found
the rectifier tube was weak and the B+ was low. I had checked it
upon initially firing up the set after a refurb and had about 200
vdc...seemed about right for the set. I got some new tubes today
and was plugging them in. I was replacing the rectifier cuz it
tested slightly weak and was ugly with rust. Bingo, it started
working down on that end, now with 225 volts. I went back and
re-checked the original tube and it had dropped off to about 160.
Duh, that one got by me!

>
> The question of my mind was -- why?

My flip answer is -- why would you want to??

Values that large are in power supply filter country, and aren't
usually very critical.

Now, for a real reason. Instruments like the AADE test
the capacitor in an oscillator circuit. High value capacitors
generally have low Q, and even if they were high Q would
result in a *very* low oscillating frequency, posing scaling
problems in the instrument.

Measure really large caps by using a series resistor and
measuring the time constant (T=RC) to the 0.67 x final
voltage point. Example: With a 10 volt supply and a
100K resistor, it will take 20 seconds to charge to 6.7 volts.
The measurement doesn't need to be too accurate, because
the capacitors aren't, either.

BTW, I am very happy with my AADE L/C meter.

73,

John, K6QQ

The AADE unit uses an L-C RF oscillator, and the microcontroller calculates the unknown L or C from the frequency change and other known parameters.

That's fine for typical values of L and C that you'd need for RF applications, and even down to AF, but it's pushing the technique beyond its limits when C or L become very large.

If you're interested in developing a micro-controlled instrument capable of measuring large values of C, then AFAIK the field is still open for an amateur project. You might want to consider other techniques, though, such as self-balancing bridges or measuring the time constant.

> Volts etc.

You've got the practical answers. For the theory, search on Paschen
curves.

The only interesting point is that the breakdown voltage starts rising
again for very
small air-gaps - that is, gaps small enough that the probablity of a
charge carrier
hitting a gas molecule and causing ionisation along its route between
the plates
becomes small.

And I don't think that you can get your plates flat enough to take
advantage of this
at atmospheric pressure.

If you look way back in the archives of Popular Electronics there was a "reactance meter" which worked by, essentially, measuring dI/dT or dV/dT. The differential was converted to a voltage read by an outboard DVM. Cheap and acurate.

1331. finding inductance

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-01 15:10:31 UTC
From: theosus@aol.com
Message-ID: <20010301101031.00294.00000375@ng-mo1.aol.com>
Source record: 54427

Is there any way to test the inductance of a coil? I have the formula for winding coils, but do not know how to test coils I already have around. I have a digital meter for resistance and such, and it will let me test capacitance, but not inductance. Is there a simple circiut I could put together, or does testing inductance involve some fancy (read: expensive) tester? If that's the case I'll just buy new ones when I need them.

1332. Looking for basket case R4C's

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-01 15:14:49 UTC
From: 2w8ji@akorn.net
Message-ID: <3a9e656b.606064887@news.accessunited.com>
Source record: 54429

By the time an R4C is suitable for my application, I mostly gut them and rebuild them. With that in mind, I hate to destroy good R4C's that someone might like like to collect.

So if anyone has any R4C's that are junkers but have parts like the the PTO and crystals, and maybe even filters, I'd be interested. I convert them to solid-state, so I give a hoot about tubes or if it is the poor 2nd mixer version (below S/N 18800 or so) of the R4C. I don't even care if any of the circuit boards are still there, cause I toss them out also.

>Some of them make Great 6 M AM amplifiers... Their just biased Class C... Easy
>fix & then retune.
>Ed G.
>KB1DQX
>(Please Remove "JUNKBLOK" to E-mail.
>Unless it's a Flame.)

If you have tetrode CB amp, it most likely has no screen
regulator...no control grid regulation...poor grid swamping....poor
power supply design....and crappy wiring. CB amps are almost never RF
tight, and most are about as safe as using a running meat grinder as a
microphone stand.

I haven't seen one yet that didn't need almost totally gutted and
rebuilt. A listen to 6 meters when the band is open will show that
many or most amps on six meters are not properly constructed or
operated, maybe that's because many are CB amps modified for 6.

If you have a triode CB amp, then there often is some hope of fixing
it for accepatble IMD performance short of rebuilding the amp.

The original poster, however, was advertising what obviously are
poorly constreucted CB amplifiers. One was two 811A's driving a 3-500,
the other had sweep tubes.

Neither would be good for six meters, and neither would be good for
amateur use. While I have no objection to people selling amps that are
intended for amateur use, that "Ham" was selling nothing other than
some junk CB amps in an attempt to make a buck.

The proper forums for attracting "customers" on top-dollar illegal CB
amplifiers are CB radio forums, not amateur forums and certainly not
homebrew forums where people most likely have a few ounces of working
brain matter. No one in his right mind would pay $650 dollars for a
single 3-500Z driven by a pair of 811's for ham use or ham
modification, or buy a sweep tube amp for $375.

There is a vast difference between offering a parts amp that can be
reworked to hombrewers at a reasonable price and posting what amounts
to an "sale notice" for what are clearly CB amplifiers in an attempt
to get a customer.

So there.

The ARRL handbook for 2001 has a very simple inductance adapter- one chip and a
few r's and c's, and your existing dmm. It's on page 26.22.

Many of the more common scanners have common IF/Demod chips in them that lend themselves to the addition of an AM detector - amplifier circuit. Many scanners cover the AM VHF aircraft band. If you purchased one of the common popular 80's, early 90's vintage scanners sold by Radio Shaft, you can obtain/order a service manual for it easy enough.

You can go two ways...

Add a seperate circuit "tack'd on to the typical MC 3357 or MC3359 chip to do your AM work. Better yet, you could modify the micro processor control lines which switch the FM and AM detectors in and out. A simple logic toggle switch would allow you to fix the detector mode of choice in line on any band.

Then you can get creative and add a simple BFO circuit to the AM detector and you will demod SSB signals. Pretty cool stuff that I've done myself in the past. Other ideas are a nice transistor add to ground a lead when signal is present, often called a COS/COR circuit. Then an audio buffer "tap" to allow connection to a tape recorder or sub tone (PL) decoder.

It's a lot of fun if your careful and go at it with a plan.

The folks at Caltech are experts on using switching FETs for HF amps.
Check their web site (just search google for class-E).

They have a parts kit they sell for $50 using an IRFP450 that puts out
500W. Other FETs reportedly may blow up, catch fire, etc.. I suspect you
could use the
IRF630's in the power supply for the amp (pulse shaper part), but I haven't
checked the specs
on the 630.

What value are the coils ? If large enough to resonate where you have a signal generator and meter , you can construct a parallel circuit with a measured capacitor and see where the voltage is at the max and work the formulars backwards for the resonate frequency. You can also make a generator using the coil and known capacitor and see what frequency it generates. Would not have to be much but a transistor and a few resistors as you are not building for stability, waveform , or power output.

When you have a large capacitance to measure it will take a long
time to charge up. On whatever principle the measuring instrument
is based, it will take a long time to measure.

If you wait long enough the capacitance can be measured as
accurately as you like.

No point. Normal electrolytic capacitor values vary so widely (with tolerances of -50% to +100% in some cases) that it's often useless to measure their values with any precision. An ESR meter like the one offered by Dick Smith Electronics is a much better instrument for evaluating the health of large capacitors.

That AADE meter kicks ass, by the way. It's the only unit I've seen for under $1000 that can measure inductance accurately down to the 1-nanohenry range. http://www.aade.com/lcmeter.htm for those who haven't seen it. At $100 for the kit, it's a real bargain.

This is actually pretty simple business, if you think about it for a minute. In fact, almost any measurement you care to make comes down to working it out.

First, if you are doing any RF work at all, you must by now have made an RF probe. If not, then you need one.

Simply connect the inductor in series with a resistor. Apply an RF source of known frequency (any old frequency) across the pair, and measure the RF voltage across the resistor then across the inductor. Voila - you now know the reactance (from Ohm's law) and hence the inductance.

Of course, it helps if you have some sort of gut feel for the neighborhood so you can guess a resistor with somewhat similar reactance, but it doesn't even have to be close, just within a few orders of magnitude. All that you really care about is that the voltages across the resistor and inductor are similar enough that you can measure them reasonably well.

Obviously, you could use a cap instead of the resistor, or even a known inductor. But with the resistor, you only have one pi * F to worry about <g>

HAMFEST March 4, 2001 - Lindenhurst, LI

GREAT SOUTH BAY AMATEUR RADIO CLUB and SUFFOLK COUNTY RADIO CLUB
ARRL APPROVED LONG ISLAND HAMFEST - March 4, 2001

LINDENHURST, LI - NY

On March 4, 2001 the Great South Bay Amateur Radio Club will again sponsor an indoor Hamfest-Computer Show. The location will be at the:

Knights of Columbus
400 South Broadway, Lindenhurst, NY.
This is an ARRL approved Hamfest.

There will be radio equipment, electronic components, computers and accessories, software, books, technical manuals, ARRL information, Amateur Radio License Exams, Door Prizes.

Advanced registration is $18.00 each table. Tables at the door are $25.00 each. Contact Walter Wenzel KA2RGI at 631 957-0218 for table reservations. NO TABLES WILL BE RESERVED WITHOUT PRIOR PAYMENT due to the space available.

General admission is $ 6.00. Wife's and children under 12 admitted with no charge.

VE - ARRL - 12:00 NOON at Babylon Town Hall, 200 E Sunrise Hwy, Lindenhurst. For exam candidates please remember to bring your original FCC Amateur Radio license (if licensed), any C.S.C.E. forms that are pending, plus a photocopy of each, pens, calculator, formal form of ID (preferably photo ID), and the examination fee, to the exam session. Current ARRL/VEC fee is $10.00, exact change is appreciated.

Talk-in will be via GSBARC Repeater on 146.685 -600 136.5 PL.

Food Service during the Hamfest will be provided by members of the Knights of Columbus Council.

Information is also available during the GSBARC 2 meter info net every Monday evening at 7:00 PM following the Newsline Report on the W2GSB repeater, 146.685 -600 136.5 PL required. You may also write to:

>I recently built a "Fox Hole" radio.

First receiver I ever built was a "foxhole radio" from the book "All About Radio and Television" by Patricia Lauber. That was about 1964-1965.

>Suprisingly, with a little trial and
>error, I started to receive a local AM broadcast
>on it. Understanding that these type of basic radio sets do not bring in
>room filling sounds, is it possible to make the
>signal strength (volume) louder? I attempted to place a .001uF cap between
>the crystal earphone, but the results were
>the same, just a very low signal. Was my placement incorrect?

You don't need such a capacitor.

Here are some ways to increase the volume:

1) Bigger/higher antenna - as long and high as possible. I had 70 feet of wire out to the crabapple tree, and about 25 feet high. WPEN was only a few miles away, though.

2) Better ground. I used the radiator pipes. Cold water pipe is good IF it's meal all the way to the water main.

3) Better headphone - a "2000 ohm" dynamic headset is the best. Low impedance 'phones don't work at all, and crystal phones may or may not be optimum.

4) More coil - the "AAR&T" design used a single layer coil of 120 turns of #26 closewound on a toilet paper tube (minus the paper, of course). I still don't know how many uH that was, but I found that with my particular antenna I could get even more volume by using a paper towel tube and more turns. Making the turns nice and even was the toughest part of the whole project.

5) Different pencil leads gave different results.

6) Different razor blades gave different results. I found that the single-edge "white" blades worked best - the blue blades didn't work at all! Clean was better than rusty. Varying the pressure of the pencil lead on the razor blade had an effect, too. As I recall, lighter was better with some blades. YMMV.

The detector in these things goes all the way back to the very beginning of radio. The Massey (sp?) carbon-steel detector used a steel needle on a pair of pointed carbon blocks. Some claim that the steel-carbon junction really isn't a

diode at all, but rather a form of coherer.

>This was a
>great homebrew to make, It's simplicity and
>history made the project all the more interesting. I am in the process of
>looking for the right razor blade with a good
>amount of "rust" for a diode. That may help, but in the meantime, any hints
>on "beefing up" the volume would be helpful.

See above. They are great fun, and the only real "radio" part is the
headphone. I actually made one using the receiver from a junked telephone once
- not as good, but it meant the thing was 100% scrounged because the wire came
from an old motor.

Hi there,

I've been playing around with various charging circuits for batteries for some time now. You can go to my kewet electric car page and vew charging graphs on the second page for the various battery formats/types.
-
If your charging a smaller battery, I would (from my experience) charge it using a voltage adjustable current limited power supply. One can achieve similar results using a simple wall wart of the proper type. Here's what I do for a typical 13 volt computer battery pack.
-
I apply a charge over a fixed amount of time through a low value resistor. For a 13 volt pack, I apply say around 18 volts through a 20 ohm - 10 watt resistor while watching the charging current. Say the current sets up at 250 milli amps (mA). Then I leave it charge for the rated time period of the battery, overcharging at such a low current level has never been an issue/problem. Heat doesn't build up like a regular NiCad Cell does.
-
I'm carefull not to get the actual battery pack voltage much above the fully charged value. I wouldn't like to see the rated 13vdc pack voltage get much above 14.5 to 16 volts during a charge. I've found a long slow controlled charge works much better over all. Batteries will "go away" when abused with overcharging...
-
I have a nice 1 amp variable voltage supply I built up, using it and the series resistor I can set up (adjust to) a slightly higher voltage (about 18v) to charge at a safe 250 mA or similar value. After a time of 8 to 10 hours, my 2.5 amp/hour pack is ready to go.
-
I received a Digital VP Laptop with out a charger and a dead battery. I've been using this method to recharge the battery for the entire year I've had the laptop now and things are great. Still like to find the right power supply for it, but I'm not into paying over $150 for a charger/adapter.
-
I use much larger charger for my electric cars. Check it out if you have time...
-

1350. using low cost ARF mosfets in amplifiers

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-02 20:09:39 UTC
From: mark <mfvernooij@wanadoo.nl>
Message-ID: <3a9ffe15$0$28803@reader5>
Source record: 54347

Does anyone has experience using a ARF444 or ARF446 (manufacturer advanced power technology) in a HF amplifier ?
These low cost mosfets can deliver rf power up to 300 watts in C class operation. When using 4 of these mosfets in parallel (operating at 300V DC) more then 1000 watts output bij 20 watts input should be possible.
Are these mosfets useful for ham radio applications?

More info can be found at:
http://www.advancedpower.com/TechSupp/App_Notes/apt9701/APT9701.pdf

Hope anyone can tell me more about this.
best 73 de Mark.

==========
So far I am very pleased with the MAHA model MH-C777 for battery packs,both
NiCad and NiMH.
When packs are NEW you have indeed to charge/discharge them a few times
before they are up to capacity.

For separate cells AAA , AA, and a slightly larger size found in for example
ISOTIP cordless soldering irons, I use a similar charger but without a
negative dV/dt sensor
Such a sensor terminates the pulse charging in the above MAHA device. When
the battery is fully charged the the terminal voltage tends to decrease
hence the negative dV/dt sensor
(BTW : the above MAHA charger I have also seen at Radio Shack ....same
price)
These separate cells I charge with a device which first discharges the cells
and then automatically pulse charges for a specific time which depends on
the cell's capacity . Time is set with a sliding 5 position switch
A 500mAh cell is pulse charged for 3 hours A cell with 1100 mAh capacity
is pulse charged for 6 hrs 30 minutes. Following pulse charging the up
to 4 cells are trickle charged ,if wanted continously.
After pulse charging the temperature of the cell(s) is approx 5 degrees
Celsius above ambient.
I bought the units meant for up to 4 AAA or AA , Nicad or NiMH cells ,in the

Netherlands in a department store for equiv. US$ 12.-
I could also charge separate cells in the MAHA device ,but then have to put a number of cells in series for the device to detect 4.8 - 6 - 7.2 - 9.6 or 12 V.

A wide range of automatic chargers for NiCads and NiMH batteries up to 16.8 V (for cordless electric tools) can be found in the Conrad Electronic catalogue , Germany.

1352. Re: help with NiMH battery charger

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-02 22:55:17 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3AA024D5.6106556B@eznec.com>
Source record: 54348

I've found the MHC777 to be a great NiCd charger. But whenever I use it to charge NiMH batteries, it decides after about 20 minutes that the battery is fully charged, even if it's fully discharged to begin with. I can get it to fully charge the battery by restarting it, usually several times. So it will charge the battery, but if you begin a charge, go away for a while and come back, there's no way of knowing whether the battery is fully charged or not.

I asked Maha support about this and got back some boiler plate about this happening with new cells. I had specifically mentioned in my query that this also happens with cells which have been cycled a dozen or so times, and pointed this out in a second emailing to them. I didn't get a response to my second email, so I assume this is a problem they can't fix.

Their MH-C204F charger doesn't have this problem, but the batteries end up pretty hot (I measured 48 C) after charging. Maha says this is normal and won't harm the batteries, even though it's above the charge temperature recommended by some battery manufacturers.

I don't have a manual for the 2600, but if you do, look for the transistor used for squelch. If they have a voltage chart, look at collector voltages on the transistors around the squelch circuitry. Find one that goes to 0V or some positive voltage when a signal is received versus the no signal voltage. If you can scan the schematic, I can look it over for you.

I have checked those & Many others. Class C is only good for FM, RTTY, CW & MAYBE AM. No good for FM. THere is an Application Note about a 50 Mhz Class AB amp in there, right? Check it out.... Combine both & You're a Homebrewer...

1355. Yaesu FT-290RII coverage modification?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-03 01:45:40 UTC
From: Hans-Christian Becker <hcb@phc.chalmers.se>
Message-ID: <020320011745403197%hcb@phc.chalmers.se>
Source record: 54352

Dear all,
I brought with me to the U.S. a Yaesu FT-290RII which I bought and used
in Europe, and consequently it covers 144--146 MHz (and has the 1750
repeater call tone). Yaesu U.S.A. tells me the only way to make the rig
cover U.S. frequencies is to change the CPU, which only costs $93 :-P.
Is there _really_ no way to reprogram the radio to work 144--148 MHz?
On a related note: Of what use is a VHF/UHF radio without subtone
encoder in the U.S.?
Best regards,
Hans-Christian W6/SM6TLH [hcb@caltech.edu]

I used to have a second hand FT-290RII (Nice radio) and it was an "A" model which I assume was for the US. Inside I noted that a green wire was draped from behind the display board and was cut in two with clear heatshrink tubing insulating the cut (Looked like factory work). This radio covered 140 to 150 MHz which seemed unusual but perhaps ideal for transverter use. In addition, an optional FT-7A board is used as a sub tone encoder-decoder board. You can probably buy an aftermarket tone encoder-decoder board and wire it in. Sub tone as you call it (PL or CTCSS) is required on a lot of repeaters in the urban areas of the US. The tone board was always a limitation in this radio as it could be set to only one tone at a time and was accessible only by removing the battery/pa and a metal plate.

Have you got the author right? Because I have a book in front of me entitled "All About Radio And Television" with a copyright of 1953, but the author is Jack Gould. It has a description of a "foxhole radio", and the coil winding is the same as you mention.

The acknowledgement page thanks the ARRL and George Grammar in particular.

I didn't have it when I was a kid, though it is the sort of book that was at the children's library in 1970 when I was looking for books on the topic of electronics and radio. I actually bought it a couple of years ago at a used book sale, for fifty cents. I'm doing pretty good lately at finding that sort of book at those sales recently.

Maybe it's because we are older, but I can't quite picture an updated book like this showing up at the children's library today. It dates from a time when science seemed far more intriguing to children of ten years old or so, and is the sort of thing that would yank kids into the hobby, with a specific mention of amateur radio. I've been thinking about this lately. There was a time when amateur radio, and specifically as a technical hobby, would show up in passing in science fiction books, and it was because the SF writers were interested in radio and electronics, along with other science-oriented hobbies like astronomy and chemistry.

These weren't hobbies for everyone, but were out there where kids could discover them. Science seems to be far more a passive activity now, at least until you actually take up a career.

I built a foxhole radio way back when...mid 60's. The article was
in a book in our Junior High School library.
One of the details I remember was that the edge of the printing on
the blade was the sensitive spot. I don't know how that logo
printing was done in those days or if they still do it, but I
suspect that it was lightly etched chemically somehow. Maybe that
gave a slightly corrosive effect for detection?.
Just thought I'd throw that in...Makes me wonder if today's razor
blades are equally suitable with their coatings, etc.. Maybe you
could find some old ones on ebay???

I have just built a Pixie2 trx for 80 m. 2 transistors and a LM386 chip.
It's fine during daytime but suffers from terrible BCI in the evenings which
makes it nearly useless.
Is there any cure for this? Have tried 4mH chokes in the LM386 input with
only marginal effect.
There are also chokes in all external leads such as speaker, key and dc
supply.
thanks

tnx for all info
Many of my WW2 receivers have had options for DF og homing, but I
can't find any complete circuits for accessory units. Have tried to
call at coast stations, but they tell me that I am 20 years too late.

Do you know a site showing such details or how to construct the
goniometer? The receivers concerned covers 75-25MHz, but long- or
mediumwave is perhaps the most interesting range to try(?)

Really? I've used RG-8x and similar cables at 100 watts on all bands
from 160m to 2m over the years with no problems. I can't imagine any
problem at HF at any reasonable SWR. I run a KW through it on 160m.

YMMV. 73, CJ K0CJ

Hallo Hans-Christian

Yeasu would love you to come with your set to them for $ 93..
But I think it would be a little to much for just removing 1 or 2
resistors..
Its a little work but whats an hour for an ammateur....hihi
Here it comes..
First remove the frontpanel from your set, including the controll knobs and
the washer for the mice connector.
Then surch for the resistor witchs is labeld 000.(just above s06).
This is resistor 02.
When you remove this resistor your FT290 covers from 140 til 150 MHz.
But there is moreYou have to remove it anyway because you need that resistor
(0 OHM) for the modification to the US frequenties..
Solder the resistor between S09 and S02 (solderpads are there already) and
your modification is done.
You now have the US frequenties in your set.
But there is more if you like to use it as I do i.e. transvertor use.
A little tabel is added to play with..
R02 R03 FREQ
=============
/ / 140-150 MHZ
/ 0 144-148 MHZ
0 / 144-146 MHZ

Try it and save yourself a lot of monney witchs you can spend on more
usefull things in the hobby

I bought some coax for my new transceiver, which puts out about 100w. maximum. The fellow in the electronics store said this cable (RG-8X, about 1/4 inch in diameter, with foam dielectric) would be fine for 100 watts. But now, I've looked at the ARRL handbook, and the section on transmission lines says 1/4 inch foam dielectric line shouldn't be used above about 25 watts. What do you all think?

From: John O'Flaherty <oflahert@toast.net>
Message-ID: <3AA14E5A.D006AAF3@toast.net>
Source record: 54365

When I got my new transceiver, I bought an antenna tuner with it, that said it would tune a wire of some minimum length to any frequency in the hf bands. I connected it up to a horizontal wire of about 50 feet long, and it tunes it (at least the indicator says it successfully tuned it). The antenna isn't very effective. I have some questions about ways to improve matters:

1. I talked to a ham about 300 miles away, and he said the antenna's performance could be improved by stretching out some ground wires along the ground. The books I've looked at mention that ground radials are good for a vertical antenna, but don't mention them in the context of a horizontal wire. Would they make an improvement?

2. If I stretched out another antenna wire in the opposite direction and trimmed both for length, I would have a dipole. The antenna tuner has an unbalanced output- if I connected a second wire to the ground of the antenna tuner and stretched it in the opposite direction to that of the first wire, would it still form a sort of dipole, or would the second wire have no effect?

3. If I made a dipole and wound a balun to convert it from balanced to unbalanced, would it still be meaningful to feed the unbalanced side of the balun with this remote, unbalanced output antenna tuner? That is, can the antenna be tuned _through_ the balun?

If anyone has any ideas about how to improve a simple antenna setup with more or less easy changes (at least until this miserable winter is over) I'd appreciate hearing them.

Look here for some power and frequency ratigs of coax.

http://www.cablexperts.com/cfdocs/tech_data.cfm?bskt=0

The ammount of power coax will handle depends on the frequency it is used at. If you are operating at less than 150 mhz, the rg-8x should be good for around 300 watts. If below 30mhz, then you are good to around 800 watts.

I am using the rg-8x on an Icom 706 to feed several low band antennas and it works just fine. I would not recommend it for long lengths at frequencies above 30 mhz at any power level due to the losses. For short lengths (under 50 feet) it should be ok for most people.

A simple antenna is the 1/2 wave horizontal dipole. That would be about
130 feet for 80 meters or 65 feet for 40 meters total wire length and
you cut it in the middle and feed it with coax. Put up a wire as high as
you can get it that is 1/2 wave long. Cut it in the middle and feed it
with 50 to 70 ohm coax. Don't worry about a balum. While theory says
you should have one, it is not necessary in most cases. If you can coil
the coax in about a 10 inch diameter circle for about 5 turns near the
antenna that will go a long way in replacing the balum. It acts as a rf
choke. In other words you don't need to convert from a balanced to
unbalanced feed for the simple antennas to work very well.

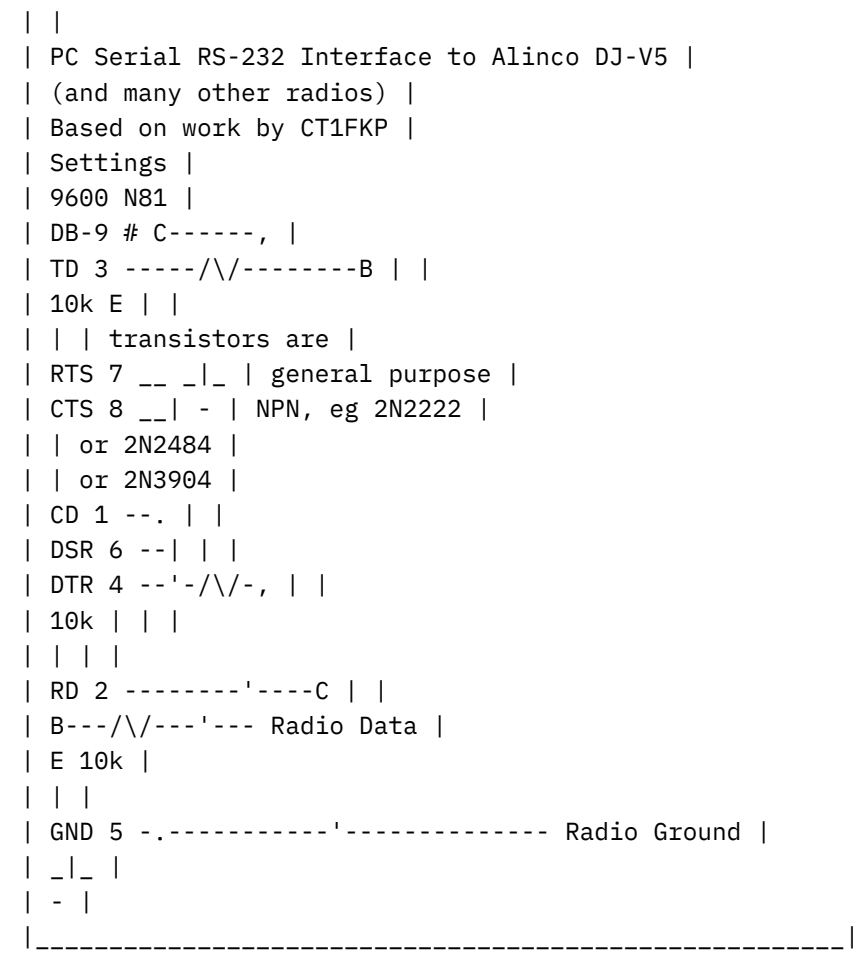
Alinco DJ-V5 PC Programming

Sylvan Butler sylvandb@hotmail.com
02 March 2001
With major contributions by Nathan Burnside

Done:
schematic and working cable
perl script to read/write all or part of memory
(the script uses the ::Serial methods, so may well be portable...)
(it does work under win NT)
ToDo:
write data editing application with nice UI
decode more of the unidentified data
==========



Modifications

Nathan Burnside writes:
Instead of:
C
TD---/\/----B
10K E
I used:
C
TD---/\/--->|----B
470 D1 E
I'm not sure why that worked, but without it, I got nothing.
==========

Connect to radio (mic jack: tip is data, sleeve is ground, see manual p.44)

Now hold <LAMP> while powering on, the display should read CLONE

Now run the software...

==========
re Protocol/data, Nathan Burnside writes:

I can now back up the entire radio on my calculator (HP48G), and reinstall the settings. I can change individual channels also, however I can't create new channels or erase old ones. There seems to be a place in memory that contains the list of channels that have been defined, and I haven't taken the time to figure out how it works. (this is all starting to get a little complex)

Basically, if I try to write to a previously undefined channel, the radio won't recognize it, and if I try to erase an existing channel, it just displays 0.000 frequency, but doesn't remove it from the channel menu. There must be some way to indicate what channels are defined. Also, programming the cell frequencies doesn't work. I've decoded the commands, and this is what they contain:

AL~F,0340,W,0,4678700,50,000,00,1F,1F,123456789012 Sample data
1 2 3 4 5 6 7 8 9 10 11

1- header Always the same for the DJ-V5
2- memory address:
0000h-01F0h configuration stuff (haven't looked at it much yet)
0200h-0F30h all of the channels (0 - C2)
0F40h-0FFFh unknown

3- W means write, R means read. (to request for the radio to send a memory address, end the command here) Eg.
AL~F0340R<CR><LF>
will tell the radio to send the contents of address 34h

4- Hex digit representing repeater split direction and mode

bit 1 set: minus
bit 2 set: plus
bits 2 and 3 clear: FM
bit 4 set: WFM
bit 3 set: AM

hex binary
4 0100 Plus frequency split, FM
8 1000 Minus frequency
5 0101 plus frequency, WFM

5- Frequency

6- Repeater frequency offset:
06 - 600 kHz
10 - 1.000 mHz
16 - 1.600 mHz
30 - 3.000 mHz
50 - 5.000 mHz
76 - 7.600 mHz

7- Don't know. Seems to always be 000

8- Frequency steps, and power setting:
together, these two hex digits are 8 binary digits. Bits 3-5 (counting
from the left as written) are the frequency steps:

00000000 bit positions
12345678

000 5kHz
001 10kHz
010 12.5kHz
011 15 kHz
100 20 kHz
101 25 kHz
110 50 kHz
111 100 kHz

bits 7-8 are power output:

00 high
01 low1
10 low2

9- CTCSS encode freq., skip scan, and DSQ encode

bit 1 - skip scan
bit 2 - DSQ encode
bits 3-8 CTCSS encode freq (I haven't done a complete table yet)

011111 67
100000 69.3
100001 71.9
100010 74.4
.....
001000 114.8
.....
011110 250.3

10- CTCSS decode freq., CTCSS on/off

bit 1 set - encode, decode
bit 2 set - encode
bits 3-8 CTCSS decode freq as described in 9.

11- channel name:
6 pairs of hex digits, one for each letter:

00h - 09h - numbers 1 - 10
0Ah - 24h - A - Z
25h - 2Fh - Special Characters in the same order as when you
scroll through them on the radio

So, that's about all I know. I haven't really looked at anything before
0200h, which is where the configuration stuff is. I'll try to post all of
this on a web page somewhere in the hopes that someone will create a
freeware application with it.

RG8X will safely handle several times 100 watts *if* the SWR is under 2:1. That's 2:1 measured at the coax not measured between a rig and a matchbox (tuner).

Source record: 54375

Thomas,

I built a controller that is driven by the FODTrack program via
a serial port. I picked the Yaesu format, which appears to be
the letter W, followed by the Az and El position in degrees,
separated by a space, and terminated with a carriage return.

Waaa eee<cr>

The Yaesu controller probably has other commands, which another
program might make use of, so I'd recommend watching what it
spits out before making a final decision.

I used the terminal program on my Palmtop to watch FODTrack
while it was running, and picked this as the easiest to code to.
The controller uses a BASIC Stamp-II, relays, and a few knobs
and meters for a manual mode for when the computer is not doing
the driving.

I don't know what the DAIWA CR-4 uses for position sense, but
there are usually two different types. One has a variable
resistor tied to the movable part, the other has a switch
that closes momentarily every few degrees. The resistor type
can be "read" with an A-D converter. The switch type, which
is what I have, requires that you count pulses to figure out
where the rotor is.

Good luck with your project,

Greg.

> know a good source? have one 4 sale?
==========
Louis, Since you don't state your location ,I would suggest you to include info on AC Voltage , power and frequency ie 50 or 60 Hz and whether the inverter is to be synchronised with the AC power grid
This is an international forum ,so would you please be more specific.

If you are US based you highly likely need a inverter for 117 V - 60Hz .

If you wish to connect the inverter output ,to the AC power supply ,using DC power from a combustion engine driven 12 V-DC generator , solar panels and/or wind generator(s) ,the inverter must be synchronised with the AC supply.

I had my son take the aluminum knobs from a Corning pH meter, mount them on a shaft on the drill press, and use a cloth with a little "rottenstone" and linseed oil to polish them up.

A totally wild guess would be to 'treat' them to some oven
cleaner, drain cleaner or other lye product. It works very nicely
for aluminum panels to get a satiny look. Of course, observe all
the precautions when playing with the stuff.

I came across a piece of lab equipment on the 'Bay -- really inexpensive. Unfortunately, upon cracking the shell there was no 120V tap on the transformer.

To make the conversion, I cracked open a "wall wart", removed the rectifiers (nice - 4 - 1n4001's anyway) and connected the 11 VAC to the secondary of the internal transformer. Works great! I figured that the wall wart xfmr was just about up to the task as the core sizes of the transformers matched, and the 0.1A fuse gave some idea of the max demand.

Oh, and by the way, remember to remove the line cord! You don't want 220VAC wiggling around on the lab/shack floor.

The strain reliefs that they use in Germany are much more elegant than those we employ in the US -- and they use a round hole!

IIRC, Northern Tool and Equipment (FKA Northern Hydraulics) and MECI Electronics offer inexpensive DC:AC invertors-- the Northern item is rated for 175W continuous and 350W surge-- enough for a laptop PC (my intended application), a soldering station or a small TV rx. The prices is $34.99 plus postage.

This one plugs into a cigar lighter, but go much bigger and you'll need to make direct connections to the battery (don't forget to fuse BOTH leads).

You must be misinterprating what you are looking at. At 30 MHz RG8X is
rated at 875W- even higher at lower frequencies. Even the smaller RG58 is
good for 500W at 30MHz.

Hi Harold,

I seem tor ecall using a dilute solution of Draino to give aluminum a satin finish.
PLEASE, try on scrap pieces first! Also do not let the piece touch any of the draino product. Think I got this from the ARRL Handbook.Of course, it is necessary to properly smooth the aluminum first- as any scratches or imperfections will still show through.
I made some aluminum end caps for my Ten Tec Omni VI+ (to replace the cheap looking plastic ones). In this case I sand blasted the aluminum w/ a very fine grit- the finished product was superb.

I don't think there was much room for misinterpretation-
Page 20.5, ARRL Handbook for 2001, first complete paragraph on the page-
(Feed methods)
"Take care when choosing coax. Use 1/4-inch foam-dielectric cables only for low power (25 w. or less) HF transmissions. Solid-dielectric 1/4-inch cables are okay for 300 W if the SWR is low. For high-power installations, use 1/2-inch or larger cables."

While I don't think I misinterpreted it, everyone who has answered (including several who answered in private emails) agrees that it's flat wrong (maybe a typo), and that RG8-X is good for one heck of a lot more than 25 W.

Thanks to all who answered.

Add me to the respondents...I've used RG8X with decent antennas up
to a kw. No problems. But when it comes to a coupla pennies/foot
difference, go fer the bigger cable. I'm in cable TV so call me
Mr. 75 Ohm cuz the samples are free. I'd yank down my cable tv
house drop (to use for an antenna) and make them replace it before
I'd pay money for RG8X. If I have to pay, then sure, I'd buy 9913
or something akin. In the meantime, this scrap 75 ohm hardline
works great (yeah. I have leads on adaptors, etc)

Not sure if it is a typo and they ment 250 watts or what but it is
wrong. There have been many mistakes made in books and it is good that
one can ask a question about it on the internet. Unless you have
several refferances it is easy to get the wrong answer.
Not only for ham radio but for many other things.

I am looking for information on the HP8554L. This is the "economy-model" of the HP140/141 Spectrum Analyzer RF plug-in which covers up to 1250 MHz. I have the 8554B manual and it does not identify the burnt component on my Bandwidth switch because the L model wiring is different in that area. I am also looking for Amphenol Series 26 connectors, the blue 24-pin jobs on the rear of the plug-ins so I can reproduce the HP extender cables which allow access to the
plug-ins under power. I need two pieces each of 24-pin Amphenol Series 26 mating connectors, 26-4101-24P and 26-4501-24S. Chances are that I could use parts with some variation in the middle number (4x01?) provided that they are mating pairs of Series 26 24-pin units. I will appreciate any leads you might furnish. The IF and RF plug-ins stack vertically using a mated pair of DBM-50 (Cannon et al.) with two coaxial inserts. I'd sure like to find a pair of these also.

Please copy to my e-mail address which is <myhamcall at arrl dot net>. Use the correct punctuation on the email address which I messed up to fool the spam-bots!
Thanks!
Allan (W1AEL)

Hi,
My name is Kees, PB0AIA, from The Netherlands.
I am looking for information on the HP8551 Spectrum Analyser. I don't know much about it, I don't even know if what I have is a complete set, or one and a half set, or that I am still missing an important part. I have three cabinets: a 8551 Analyser, a 8551B Analyser, and a 851 display unit. Do I need any more equipment to get a complete working machine? Does anyone have an operators manual I could buy a copy of? Is it possible to use a general oscilloscope in place of the display unit? I would like to get this machine working again, or both of them if I have two.
73, Kees PB0AIA

The problem with measuring RF inductors is they really should be
tested close to the operating frequency. The most accurate way to do
that is to look for resonant frequency with a grid-dip meter or
signal generator with a detector.

The effective inductance chages somewhat with frequency.

At frequencies far below self-resonant frequency of an inductor, the
"IC chip" type measurement devices or meters are OK.

I use different measurement methods depending on the application.

What are you trying to measure, and what frequency will it operate on?

Hello. I am in the process of converting an Intech 2500 marine radio to
ham band use.It uses a Collins mechanical filter to derive the USB
signal. LSB was available as an option and replaced the AM filter
with an LSB Collins unit. I have the service manual
but it does not list the Collins P/N for the LSB filter.
The USB unit's P/N is 526-9897-010.
From the filter list @ http://www.wa3key.com/filters.html#master
I have determined that the correct filter will be a 526-9939-010.
If this is incorrect, please let me know. If you have one for
sale or know of where I can get one for
less than a kings ransom, please let me know.

HF-281 & HF-282 526-9897-010 USB 1.95

5p6 = 5.6 p ("five picofarads and six tenths")

4K7 = 4,700 ohms ("four thousand, seven hundred ohms")

2n2 = 2200 nanofarads

etc.

Although I was born and live in Leftpondia, I prefer the Rightpondian nomenclature. Generally, the letter for the UNIT replaces the RADIX character ("decimal point" in Leftpondia) Especially for 3d generation photocopies and low-res JPEG schematics, you will never mistake a decimal point for a "flyspeck"

Personally, I have a hard time remembering exactly how much a nanofarad is!
(the term is relatively uncommon here in the States, usually using 1000pF or
0.001uF instead..)

(wouldn't 2n2 be 2.2 nanofarads? i.e. 2200pF or 0.0022uF)

From: Kevin Hastings <hastings@nbnet.nb.ca>
Message-ID: <HNCo6.11242$br1.72985@sodalite.nbnet.nb.ca>
Source record: 54301

I picked up the guts of a Ramsey FX-146 10/91 Rev 1.3 at a local junk store, and need help with the frequency-setting diode matrix, and mic pin-outs. I'm betting this is all on the web someplace, but darned if I can locate one thus far.

Can anybody point me to some reference so I can test this thing?

hastings@nbnet.nb.ca

1405. Ramsey FX-146 diode & Mic information query, or web site

>I see many schematics mostly from Europe with the capacitor values written
>as 5p6 or7p5.

Europeans like to simplify by putting the U.S. "ending" in the middle instead of a decimal point, i.e. 5K6 Ohm rather than a 5.6K Ohm (also they're smart because often the decimal is hard to see and in the above example, it could look like 56K rather than 5.6K in the US., but in Europe, it's plainly 5K6 or 5.6K with no questions.)

Same for capacitors = Capacitors 5.6 pF in US is 5p6 in Europe.
Hope that helps a little.

Better than drano is red devil lye. The draino I have seen already
seemed have some Al chips in it. Lye is commercial grade sodium
hydroxide, a very basic/caustic compound.

To reduce corrosion filming, many polished Al knobs are coated with a
thin lacquer/acrilic which must first be removed. Also, if the Al is
heavily anodized (especially if it is also scratched), you might get
uneven etching.

When caustic etching some AL alloys, a dark film may develop. I would
guess this is from the alloy metals which are not so agressivly
attacked by the hydroxide. I have found that a quick dip in a nitric
acid solution will "clear" the film nicely. Hydrochloric (muratic)
acid may also work - haven't tried.

Do beware! these chemicals are dangerous if not handled properly.
Also, the Al/caustic reaction is pretty rapid and somewhat exothermic.

Easy to remember using scientific notation...

milli= 1 x 10-3, micro = 1x10-6, nano = 1x10-9, pico = 1 x 10-12

Heck, I go back to the days when pico was expressed as micromicro eg
10 pf = 10mmfd ;)

Well, Woody, you must be searching way back in the cabinet under
the sink. Drano 'brand' stuff nowadays is pretty lame and real
Red Devil lye is outlawed in most states since some project mother
may mistake it for ham-drink or lemonade. But EZ Off has yet to
be confused with cheezewhiz and is still on the market...up till
now.
God help us...he sure seems to help everybody else.

> Looking for any input about constructing antenna supports for wire
antennae.
> You guessed it, I have no trees. I like to experiment with different
types.

Bill,

I have the same problem. I live in a very windy location
and was not comfortable with the typical wooden pole.
I wound up buying a "hot stick". This is the telescoping
fiberglass pole that power company linemen use to reset
circuit breakers, operate switches, etc. Mine is 30 feet
long (high) and telescopes down to 5 feet long. It is very
strong, and supports my inverted-V fed with window line.
No guys, but it is bracketed to the house at the roof line.
Not the best antenna, but any antenna is better than none!
In the past few months of *very* casual operation, I've
worked some fifty countries with five watts CW. If I'd
been trying, I could have easily worked DXCC.

One downside, they are expensive. You might find a
friend at a power company who could get you one that
they are retiring.

73,

John, K6QQ
Alturas, CA, at the corner of 299 & 395.

1413. Signal Generator Basics

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-05 06:39:54 UTC
From: Ron Hubbard <hubbard_ron@hotmail.com>
Message-ID: <97vc3m$qbohb$1@ID-43450.news.dfncis.de>
Source record: 54310

I want to buy a decent (but cheap) signal generator and the three I have my eye on-- the B&K 2005B, the SG-4160B, and the Protek model B-813-- all look exactly the same externally and apparently has the same specs although there's a wide price range between them.

Does anyone know 1) if these three signal generators are the same electrically and 2) what is the external crystal socket used for?

Thanks.

Try this link:
http://www.nlsa.com/autotracking.html

I found a bunch of info on various rotor command sets a while back and I think I got most of it by following the links on this page. Maybe I did some searches too with information I found here.

Can't remember the details now. Hope it helps.

I am trying to locate a manual for the Motorola VHF Linear number TLD6622A. I believe it was part of a system and might be included in its manual. The tube is missing and its heat sink assembly and I am trying to identify the missing parts. Will pay for copying and shipping or reasonable cost of original. Please respond via email. Thanks Don KB6GQA

These days it's so simple and cheap to do something with a PIC it's hard to imagine wanting to fool with an array of diodes. That's probably why you can't find a circuit. The PIC can do the timer, IDer, and control logic for the repeater, probably less than $10 for the whole circuit. Cheap way to avoid fooling with hundreds of diodes.

A random wire can be a decent antenna with a good counterpoise (i.e. a ground radial system). However, it probably will never match a decent resonant dipole. The real advantage is that it works approximately the same on several bands.

If you are going to work a bunch of bands, put together some sort of ground system, and get your wire up high, and probably longer. A thing that looks like a dipole but isn't resonant is called a doublet, and will work reasonably well, too.

But if you tend to operate on just a few bands, put up dipoles for those bands. You will find it a lot more satisfying.

1420. L.O.S.A - List of Stamp Applications [010305]

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-05 17:42:11 UTC
From: cjX@hth.com
Message-ID: <3aa3cfd7.3819170@news.sverige.net>
Source record: 54317
Cross-posted to: comp.robotics.misc,comp.home.automation,sci.electronics.misc,rec.radio.amateur.homebrew

Hi,

Below is the latest index of L.O.S.A and it now contains 220+
BASIC Stamp projects. You can download the complete L.O.S.A
from the following places...

WWW:

http://www.hth.com/losa/

FTP:

ftp://ftp.parallaxinc.com/pub/text/losa.txt

1.0 What is L.O.S.A all about?

This list was started back in -95 when I heard about (more or less)
uniqe problems that was solved by using a BASIC Stamp. Especially Guy
Gustavson's story (see #001) about how he saved his beloved cat Kesha
gave me the inspiration to start writing L.O.S.A. I hope Kesha still
is alive and having a great life. Now 5 years later there are 190+
applications described and I hope you will enjoy reading all (or
parts) of them.

The main purpose of this list is to get an idea of what other people
are using their BASIC Stamps for and maybe get some inspiration or
hints for your own projects. Some of the projects described in the
list also have links to source code and schematics for download.

1.1 How can I contribute to this list ?

If you have done something (big or small) with the BASIC Stamp that
you are willing to tell others please use the form given below and
write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

Visit the following Web site and fill in the contribution form...

http://www.hth.com/losa/

1.2 Why are some links dud's ?

Since people changes their e-mail and web addresses some links may be
dud's. If you previously contributed with one (or more) of the

applications please take a quick look and check your e-mail address
and/or web-links. I'm only able to keep the list updated if I'm
informed about changes, thanks in advance.

1422. A Plate Supply with Headroom?? American Transformer Model 26579

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-05 19:34:42 UTC
From: yardleyite@aol.com
Message-ID: <20010305143442.16845.00000581@ng-mj1.aol.com>
Source record: 54318

Could anyone on this thread possibly help me identify the following plate supply? If possible would anyone know the original application for it? I plan to build am amp using a single 4-1000A and am trying to find out if the current plate supply would be sufficent. Any information will be greatly appreciated. If possible please email all replies directly to me at: yardleyite@aol.com. I was able to get the following information from the supply:
Thank you and 73 de Joe Cro N3IBX

American Transformer Company Model 26579 Primary 105/ v. Secondary 6200/ vt 2kva. The primary has 4 insulators, all common to each other, it appears to be 105,110, 115 vt taps? 115 vt on primary gives steps of 6200 vt on the secondary There are 2 large insulators on secondary and center tap appears to be to the case.

Hi, I am looking for information on an Icom IC-211, Mine has a interesting problem. I can change frequency but the display and frequency skip around I can go from 144.130-144.199.9 ok but then it junps to 144.220.0 it seems to skip over everything in the 14X.X00.0 to 14X.X19.9 range I resoldered all the connections in the PLL and the board for the display, Display drivers. I suspect a component failure on the display driver board? Does anyone have any info? maybe a schematic?

Thanks

Hi, Allan -

HP's RF spectrum analyzers were and are made by their divisions in Santa Rosa and Rohnert Park here in Sonoma County, California. The local ham club is the Sonoma County Radio Amateurs (http://www.cds1.net/scra/). If you send them a note, I suspect you'll find all sorts of expertise.

With over 100 engineers in just their Signal Analysis Division (spectrum analyzers) when I left there in '89, they have quite a few very active hams, including several who have published widely. They're "Agilent" now, but still a good bunch. And the club is first rate.

Best of luck with your analyzer!

Is it a conduction cooled PA? I have a Motorola PA that uses a 8560AS conduction cooled tube I do not have the schematic but I did draw one out I use it on 144 Mc. SSB
Excellent P.A. for 2M a little change should be made in the output coupling but not really nesisarry..,

Hi. mY name is Josh. I have been attending Washington State University for some time now in the Electrical Engineering program, and have noticed a problem. In all the courses I have to take and can opt to take, a mere 2 deal with RF, 1 only vaguely! This frustrates me, as I had very much hoped to know the most about RF of any other sub-fields in electronics with this college experience. Is it still that mystical of an art, or do we just have a poor radio program?
In that vein, does anyone know of any good books they can recommend, and/or web sites that teach the basics and on up about radio? I would like to make a simple VHF reciever as a project. I have made other projects dealing in RF, like an FM transmitter, but never without the help of a schematic from someone else. It almost seems like the reciever will be more complex than a transmitter...something I always thought would be the other way around. But, I am very anxious to get a grip on the knowledge that I have wanted for so long, but has eluded me at every turn.

-Thanks for your help

Both the ARRL and the RSGB have excellent general 'handbooks' as
well as great VHF manuals. check www.arrl.org, I think you can
get them there.
Good luck,
Bill

Hi Jim,
I don't think soldering all the connections will help. Sounds like classic bad plated thru hole problems, on both the pll and display. The real cure is to take the display and pll boards out, and push a wire through each and every via and solder it on both sides of the board and then put them back in the radio. A job for the "not faint of heart". But that will fix up most of the intermittant problems with that rig and the IC-245 which used the same pll assembly. Good luck, they are a dog to work on but decent radios when they are working right. Oh, use good ESD protection as the pll processos is not available anymore. It's cmos and if it dies, the radio dies with it.

Wally

Since you said VHF and heat sink, I'll throw out that the tube was
probably an 8560 and the unit a vintage early Micor or late Motrac Base
Station Repeater type. The often white block inside the pa cab is
beOxide, just be carefull not to sand or breath dust from any broken parts
of it.

Hit the flea markets and have a look around for the Motrac Series of high
powered base / repeater units. God knows I worked on enough of them in my
day...

I've converted the Heathkit SB-230 conduction cooled amplifier to run on
the 8560 tetrode.... similar mounting and lots of gain when set up
properly.

: charge some AA batteries ;-)
: 73,ed.

Actually, NiMH and NiCads do charge different with the NiCads being more straight forward in the way they act. IE I know what to expect from them NiMH are not very forgiving and the dont send out much of a signal when your abusing them. Hence, I control the NiMH charge more closely than I do NiCads. Power supplies are easier to use than regular chargers if you have a fixture made up.

Manuals: Ed Matsuda (ematsuda@earthlink.net) may be able to help.

Cables: All HP14xT and 8505A cables can be fabricated by George Kerber
(glkinst@earthlink.net). He can also tell you where to get the parts to
make your own (I seem to recall finding some of the D-sub shells and/or
mini-coaxial fittings at Digi-Key).

www.radioshack.com has 602's for a reasonable price - they are an exact replacement. 602's and 612's have been scarce lately, but the reappearance of 602's at rs is a good sign. The 612's are basically the same part with fewer tests. As a result, they sell a little cheaper than the 602's but not much. rs's price on 612's is 2.25 vs. 2.75 for the 602's, but they don't have 612's in stock.

You can also get 602's are www.rfparts.com, but they are like 8 bucks - yikes!

The advice several posters have given on the Handbook is good, but beyond the basics, the Handbook isn't a lot of help with design.

"Introduction to Radio Frequency Design" from the ARRL is pretty good, but it's also pretty tough slugging. Still, it may be what you are looking for. It may not be as tough for a EE as it was for a ChemE <g>

An excellent source, tho a little slow, is the Low Power Amateur Radio reflector (http://qrp.lehigh.edu/lists/qrp-l/). This reflector often discusses design issues, but since it happens when it happens, it isn't very direct.

Another good approach is to study what others have done. There are a lot of kits on the market with their manuals, including schematics, on the web. Some even have very well detailed discussions of the circuits and design choices. If you can get someone of similar interest, getting together and comparing different schematics from the perspective of the design choices can be very instructive.

The best plan, in my opinion, is to learn Spice (you probably already have) and just do it. Nothing teaches quite like experience.

But if you look in the upper left corner it says it's out of stock. That's the problem everywhere.

Whoops - the 602's are out of stock, too. They weren't a few days ago, but the QRP-L caught wind of them, so I guess they drained the stock. Not too surprising.

Must admit, haven't looked for any lately. I work at an R&D lab which is relatively well stocked with the *real stuff* - and has fume hoods. I am gettin' pretty $#%$#^ tired of laws to protect us from ourselves (and make Darwin obsolete). I certainly want to be informed... Then let me take it from there!

And EZ Off... Supprised you can still get AEROSOL lye (is it still?). Could mistake that for hairspray too! It *would* put an end to bad hair days :)

Give me the days when, as a kid, I went to a local chemical supply house, walked to the counter and asked for 2 liters of conc nitric, 1 liter of conc sulfuric, anh (hummm) a liter of glycerine. Their reply was: "Anything else, kid?" I decided I didn't have the proper temperature controlled baths and went no further - at least with that particular formulation.

1444. Alternator whine help please

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-06 12:19:27 UTC
From: Rod Marsh <rredbeak2@dingoblue.net.au>
Message-ID: <3aa4d626$0$25469$7f31c96c@news01.syd.optusnet.com.au>
Source record: 54341

Hi all,My son has Alternator whine in his sound system [not bad but annoying].His amplifiers are mounted and well grounded under the rear speaker tray.
He has 2 Amplifiers:- one for the 4 speakers and one for the SUB.Power to drive the amps are taken directly from the battery in the engine compartment [vehicle battery] and i told him choke the whine off at the firewall with 2 [one each + line] ferrite chokes with multiple turns etc.

His Alternator is factory filterred etc and had NO trouble before the amps came along,he is using the same radio.

Am i correct in assuming the + leads [2] are carrying the whine to the amps then being amplified thereafter etc??? Am i correct in assuming the ferrite chokes should be placed at the firewall or is there something else i need to consider please?

Before he buys the chokes have i advised him correctly??
cheers Rod VK4XI

Jim, if I read your post correctly, then the actual xmit/rcv frequency is skipping over part of the band. If that is the case, I shouldn't think your problem would be in the display circuit as that part is just some BCD counter outputs that are fed to decoder-drivers and then to the LED display.

Does the problem remain the same regardless of whether you are in simplex or duplex, and regardless of what mode you are in? If it does, then your problem is probably somewhere in or around IC1.

Mine has been acting strangely for a year or so. I can only tune it using the RM-2 remote controller, I haven't yet looked to see if I'm getting any pulses out of the tuning dial.

Good luck,
Ed - N5KZW

You can use RG-174 (the tiny stuff) at 100W on HF if the SWR
is 1.5:1 or lower. The only problem with 8X at high power
is that you can ruin the coax if the SWR is too high.

CJ (cjr@visi.com) wrote:

Source record: 54346

Hi,

I just made something that a friend of mine tells me he thinks is called a "monimatch," but he isn't sure. Can someone tell me some more information about the monimatch? A web search didn't turn up very much at all, except that I think he might be right.

A QST periodical search turned up 14 articles, and all but 1 are from the 50's and 60's (the latest is 1986).

What I've done was to etch a 50 ohm stripline onto a PCB, along with two etched pickup traces on either side of the stripline, in an attempt to couple to a sample of the forward and reflected voltages. It works, but now I want to find out more about previous work on this.

Thanks for any info,

This is a Motorola Maxtrac UHF 40-watt 2-channel mobile commercial
transceiver. These are going very quick, only a few left!
Model number: D44MJA73A5CK. This unit is in PERFECT condition, works and
looks
like a brand new radio. Bench tested and scored a perfect 10. No knicks or
scratches. This radio is PC programmable and includes all CTCSS (PL)
encode/decode and DCS (digital PL) capabilities. Frequency range is from 430
MHz
thru 480 MHz, including the 70 cm Ham band and all GMRS and FRS frequencies.
With a high output power of 50 watts, 40 watts safely without risk of
overheat.
With 5 pin accessory jack, mini-UHF coax connector (standard),
quick-disconnect
power plug (standard), includes a PL-to-ground commercial microphone.
***THIS
RADIO CAN BE COMBINED WITH ANOTHER RADIO AND A REPEATER INTERFACE MODULE TO
CREATE YOUR OWN HAM/COMMERCIAL/GMRS REPEATER.*** Payment options: I accept
Billpoint, Paypal, MO and certified checks. +$15.00 shipping Textronix Inc.
$250.00 Firm, peaked, tuned & Aligned for maximum recv & transmit!! These
make excellent repeater radios or 70 ctmr ham for high power long range &
super recv! Dan (806) 481-9319 cactus4christ@hotmail.com

You can ruin any coax if the SWR is too high when running high power.

How high an SWR do you mean, and how much power?

Source record: 54250

The Monomatch was one of the first SWR meters for hams. I believe it
was designed by Lew McCoy, a ham that wrote many articals for the ARRL
and QST about antennas and feedlines.

It is made in many forms but the circuit is basically the same. One of
the simpliest versions was to take a piece of coax about a foot long and
take off the outer jacket. You could then push 2 pieces of enameled wire
under the braid. One end of each wire was terminated with a resistor
and the other end with a diode. A meter, switch and pot were about the
only other components needed.

The only drawback that I can remember is the sensitivity went up as did
the frequency and you also reach a point where you have to use shorter
and shorter lines for the higher frequencies.

Many of the simple just SWR meters (not the ones that read forward and
reverse power) have been made and sold using a similar arangement of the
printed circuit.

There are a few good books about radio design. One of them is Solid State
Radio Engineering. Another one is Communications Receivers, bu Rohde
Bucher, and Whitaker. A good introductory book is Introduction to Radio
Frequency Design, by Wes Hayward. Another good source of ideas is the ARRL
Handbook; this book has information derived from many sources.
These books will give you an understanding of what "goes on" in a receiver,
but the best way to learn is by building some of the circuits. This is the
only way that you will be able to take a circuit that looks good on paper,
and create a working model!

If thats true then as I recall the NTE123AP is also a sub for the
2N2222(A). These can be had from BG Micro for 12 cents each or 100 for
$9.00. If you don't mind taking (in my opinion) a small chance you could
go to Radio Shack and pick up there pack of 15 NPN transistors for
$2.29. They spec similar to the 2N3906 which I believe also crosses to
the NTE123AP

1456. WTB heatsink for 3 or 4 xistors

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-06 23:05:24 UTC
From: enigma_y_2000@yahoo.com
Message-ID: <3aa56c63.14858254@news.usfamily.net>
Source record: 54252

Hi,

I need a heatsink that I can fit 3 or 4 T0-3 transistors onto. A bonus would be if it came with premounted NPN transistors something like 2N3055.

I'm building a DC supply for a boatanchor and need parts, so if you want to sell an old heatsink, please email me.

Or if you have a supply capable of putting out 28 VDC at 12 Amps, and the price is right, I might purchase that from you.

Thanks in advance,

Bob

There's a subtle distinction between the NTE123A transistor
and the NTE123AP: the former is a low power transistor [like
the 2N2222} but the latter is an audio/VHF power transistor.
He may pay less, but it may not be what he's looking for.

Source record: 54258

Rod,

The ferrite will work well for RF but will not likely be very
effective at audio unless REALLY big with many turns.

A source of alt whine can be a bad diode or a battery with a high
internal resistance. More likely in this installation is a ground
loop. Power should be supplied by both a + and - wire from the
battery. Even doing that, I have experienced whine. It went away
when I isolated the remote amp from the car chassis. The only grounds
are the - wires to the battery and line level feed wires (shields)
from the radio. For really tenacious problems, isolation transformers
may be necessary in the line level feeds from the radio.

Actually, the system with etched lines coupling into the main 50 ohm trace is often referred to as a directional coupler.

This is a common approach used in UHF and microwave equipment. You can measure both the forward power on one coupled trace, and the reflected power on the other trace. Of course, the detecting device tends to have troubles since the amount of energy picked up on the coupled trace is low enough that most diode detectors do strange things......

If you can track it down, there was an article in Ham radio, November 1987, showing how to build a nice RF voltage detector that can be used to measure these low levels and maintain an accurate reading.

Rod

Try lifting the earthing connection at the amps - it may well be a
ground loop problem. remember, the alternator charge current presents
a longitudinal voltage across bodywork. no matter how hard the
manufacturers try <g> to minimise costs - whoops, problems ;-)

Hello Josh,
Congratulations, you chosen a very good first step in learning about RF.
(asking others who know)
The amateur radio community is a great resource of information and most hams
love to share their knowledge.
I am not an engineer, just a tech, so I don't know if it is just your school
that is lacking in teaching about RF, But don't despair, you can do it.
The other responses to your ping for help are correct, the ARRL has some
great books.
But I seem to get the most out of the manufacture's data books.
National Semiconductor, Motorola, Texas Instruments.... just to name a few.
These books have sections in them called "Application Notes" that describe
how to use their devices in real world applications.
Many applications discuss in depth, designs around the real world chips and
devices.
Now days they are also on line, but the nice thing about the books is that
you can page through them and read them in your leisure, keep them in the
bathroom, read them on lunch break, or read them in bed.
Your school library should have them, but if not, ask the electronics lab
tech, he probably has a couple on his bench.
Also, Many radio clubs have "Elmer's", that is the term we hams use for some
body who can and will show you what ever they can about radio.
Your school may have a radio club, but if not, you can look on the ARRL web
site for the nearest club.
73 (very best wishes)

Previous suggestions were good. I'm going to suggest two books that I haven't checked for current availability. These are not "start from zero" books but have lots of practical info once some of the basic concepts are understood. They are more practical than theoretical in their presentation.

RF Design Guide Systems, Circuits, and Equations
Peter Vizmuller 1995 Artech House, Inc.

Radio Frequency Transistors Principles and Practical Applications
Norm Dye and Helge Granberg 1993 Butterworth-Heinemann

I hope they are still findable. Good luck in getting started and having fun building and playing.

1467. Help with analyser hard copy

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-07 12:11:34 UTC
From: Jeff Smith <jhsmith@ns.sympatico.ca>
Message-ID: <3AA623B9.ECF5D90B@ns.sympatico.ca>
Source record: 54264

I need some ideas on obtaining hard copy from an older HP spectrum analyzer.

I have outputs from an older spectrum analyzer that I wish to couple to a PC via sound card inputs. (I want to develop hard copy capability.)

These outputs were intended as X-Y for a small pen plotter, and you can control the sweep speed , etc. from the analyzer. What would be great is a piece of software that emulates a plotter by using the sound card inputs. Any ideas ?

Ideas, yes; solutions, not yet.

It would indeed be nice to take the X-Y outputs from the 8552 IF plugins, and feed them into a PC where software could provide many of the facilities of a modern all-digital analyzer:

* Clear, complete traces from very slow sweeps (useful when the storage tube is getting a bit tired)

* Averaged multiple sweeps

* Peak hold for transient measurements

* Notation of measurement conditions on-screen

* Screen capture to file

* Output to printer

* Subtract a stored trace from the current trace (normalization, creates a flat baseline for swept measurements with a tracking generator or return loss bridge)

Since the X and Y outputs are not audio, the sound card inputs to the PC cannot be used. However, it would be simple to build a small 2-channel analog-to-digital converter to interface to the parallel port (the serial port would be too slow for 8-bit or better resolution at high sweep speeds). The detailed circuit is mostly a matter of deciding how the ADC should interface to the PC software.

It's on my project list, but I can't help feeling that someone, somewhere must have done it already. There are thousands of those units out there, many passing into the hands of hams, and the RF performance is still excellent. As Jeff identifies, it's just the analog output that's holding us back.

There doesn't seem to be anything on the web... unless someone here knows better...

Unfortunately, the pen plotter outputs are DC, and most sound card inputs are AC coupled, so don't respond to DC. What you would need would be an industrial interface card AND some custom software. You could probably find a used DC plotter cheaper.

A few weeks ago I started work on an HP7470 plotter emulator for Win32.
Right now, I have it working with the HPGL command subset used by the
Tek 492 / 494 / 496 analyzers (except for some slight text-formatting
issues which don't really hurt anything). The source and executable
code is on my site below, in case anyone with a 49xP analyzer wants to
check it out.

I've also found that HPGL-compatible instruments can dump their plotter
output to a modern LaserJet or other PCL-compatible printer, by
prefixing the binary dump with the escape sequence 0x1B, 0x26, 0x6C,
0x31, 0x4F, 0x1B, 0x25, 0x23, 0x42. This will put the printer into
landscape mode and configure it for the older HPGL command set. You can
get very nice hardcopies from the Tek analyzers this way -- all you need
is a short program to read the plotter data from GPIB and dump it to
LPT1 with the above escape sequence.

Not necessarily. If you can find and remove the DC blocking capacitors from your sound card's input path, there's no reason why you couldn't record down to DC. Older, simpler sound cards like the original Sound Blasters should be trivial to work with.

Another alternative that wouldn't involve modifying your sound card: use the plotter X/Y outputs (typically 0-5V or 0-10V) to drive a simple V-to-F converter. http://www.exar.com/products/XR4151.html from JDR Microdevices or Future/Active might be one option. Record the resulting audio with the sound card and count the zero crossings in the .WAV output to calculate the input frequency. Sampling a 44 kHz stereo recording in 10-millisecond chunks would give you close to 8 bits of precision. Longer counting intervals could be used for higher precision at slower sweep speeds.

There is ALWAYS more than one way to skin a cat in the PC world, without resorting to a lot of custom software or hardware.

You may be thinking of SPlot http://www.swplot.com/splot.htm. It's
powerful, but expensive to register ($65 per plotter model supported),
can't export simple .BMP / .GIF bitmaps, and seems to work only through
its GUI rather than a (much more desirable IMHO) batch or command-line
mode.

Still a pretty nifty piece of software.

1479. Strong Signal performance of Minicircuits PSC series Splitters?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-07 20:37:36 UTC
From: Dan Rae <rae4@ix.netcom.com>
Message-ID: <3AA69C10.8030208@ix.netcom.com>
Source record: 54276

I recently picked up an MCL 12 way splitter, and was hoping to use it to homebrew a 12 way HF receiver multicoupler, if the strong signal handling would be up to it. I could not find any data on the MCL web site as to the IP3 and IP2 performance of these units, and wonder if anyone has been down this road before. I was going to precede it with a strong 12 dB gain amplifier and maybe a LPF to keep local TV and FM broadcast stations out of it.

Thanks in advance for any input, and yes, I know I've only got one pair of ears :-)

Dan AC6AO

I find that a technician who has a true interest in RF often knows more about
RF than some engineers. Also, interested people are more intuitive.
For example, ask a person what happens when you take a 1/4 wave length
transmission line, short one end, and what do you see on the other end?
This classic example is often answered by technicians correctly- the other
end looks like a very high impedance. Some RF engineers who are good
with calculus can't answer that off hand.
Al, an electrical engineer

Hi Bob..
I have a couple of those heat sinks that are pictured in the Handbook, I think they are already drilled for TO-3 transistor cases. Drop me a line if you are still interested.

Yes, it will show the extra digit.

The bad news is that mine was enabled when I bought it, so I
am not aware of the modification, but I do know there is
one. Good luck.

Hi It, just depends what you want to spend on it. Can I suggest that the cheapest alternative might be a Pico Technology 8 bit ADC (abt 49 GBP), and a copy of Pscope (which is available free from their web site). The software provides print out facilities. I am not sure whether it is possible to 'scale' the axes although this is available on Picolog software.

Are you sure you really mean "11m" to 2m? If your not a licensed Ham fat chance you're going to get any help here. If you are licensed, and your going to use a stock CB radio, the only mode you can use would be SSB. As far as I know AM is not permitted on 2m. If you want to run FM, then you need to modify the CB.

Since when wasn't AM allowed on two meters? It was used before FM. CW is
allowed on two meters also.

> As
>far as I know AM is not permitted on 2m. If you want to run FM, then you

That is incorrect. The first 100Khz of 2m is reserved for CW, the rest of the band is open for any mode. You won't find a lot of activity on 2m AM, just some special clubs running old Gonsets, Hallicrafters, Heath "lunch boxes" and the like. But, it's perfectly legal if you are licensed.

>Can anyone know how to build a transverter from 11m band to 2 m ham band?

Spyros,

Go here: http://www.tentec.com

I have built three of TenTec's 20M to 6M trnasverters for friends and
myself and it's an excellent kit.

The also have other frequency combinations. The transverter will allow
you to operate any mode on two meters that the 10 meter rig is capable of.

If you are trying to use an 11 meter (CB) rig as the exciter, I'd really
suggest you convert it to 10 meters first. It will reduce interference in the
long run.

73 and good luck

Hello Spyros,

You may get some ideas from one of my projects, a 20 meter to 6 meter linear transverter. Local oscillator and filter frequencies would have to change, but the principles are the same. The output stage is a 18 watt "brick" (similar RF power hybrids are available for 2 M). I don't know about parts availability where you live, but MMICs, mixers, etc. are available here from MiniCircuits (http://www.minicircuits.com/). Also "Down East Microwave" carries many of the "bricks" (http://www.downeastmicrowave.com/) and other parts. Don't know about exports...

For my project, go the the homebrew section of my web site (below).

The amateur literature is full of 28/144 Mhz transverter circuits that
mixes the 28 .. 30Mhz band with a 116 MHz crystal oscillator and
transfers it into the 144 .. 146 MHz band. If your input signal is in
the 27 .. 29 MHz range, change that oscillator frequency to 117 MHz.

One problem with the 28/144 MHz transverter is that the 5th harmonic
(e.g. 5x28 MHz = 140 MHz) will fall outside of the 2 m amateur band.
This signal can quite easily pass through or be internally generated
within a transverter.

It is a good idea to use a transverter circuit with some selectivity
(at least some low pass filtering at the transverter input at 28 MHz)
to prevent harmonics from the CB radio to enter the transverter.

Use a good transmitter mixer, such as a double balanced diode ring
mixer (e.g. SBL-1) that will have a relatively good isolation from
input port to output port and from local oscillator port to output
port. This will reduce the 5th harmonic leakage and also the 116 MHz
leakage. In addition, this mixer will produce less own spurious mixing
products than simpler mixers.

Use some bandpass filters in the amplification stages between the
transmit mixer and final output transistor. Using only a low pass
filter after the final output transistor is not enough to attenuate
spurious responses near or below the 2 m band (such as the 116-28=88
MHz image response).

Depending on what distance you want to work, either don't worry about height
of a horizontal antenna and work locals (within a few hundred miles) using
high angle radiation (presently popular is the buzzword NVIS=Near Vertical
Incident Skywave) OR if you want to work DX use a vertical, then only one
support is needed and the support is the radiating element. A full quarter
wavelength vertical can easily be mechanically sound without guying as low
(in frequency) as fourty meters. You just have to have good foundation (in
the ground or part of a building) to mount it to, AND a good radial system
if you want it to be efficient.

If you go to Maxim's website:
http://www.maxim-ic.com
and look in their apnotes there is an XY plotter and plotting program (it's in C++ I think).

I picked up an HP7475a plotter a few weeks ago for $20 (cost more to ship) and subsequently picked up the manuals and the HP PCL5 manual which contains the HPGL instruction set. This has turned out to be a great toy. You can communicate quite easily to the HP7475a via the serial port with any text editor. An HP7475a and a '486 laptop will give you enormous flexibility compared to what was around when HP started busing things together.. (Why is it that dad gets the '486 while junior has an 833?)

John, you are making this much too complicated. If you remember the formula
for a dipole, build one to the lowest frequency you want to work and feed
the antenna with coax. Your tuner will now tune everything that is legal
for you. It will not be the most efficient antenna, especially the further
away you get from the design freq., but you WILL get on the air and you will
be heard!

HELP

I just bought a Odetics GPStar Time and Frequency System on ebay. I haven't
received it yet but I know the power supply and antenna are missing. The ad
said it requires +12 and +5 volts which I have. In additon I have a MICRO
PULSE GPS N 1334NW/A GPS antenna that I'm going to try to use with the unit.
My main
interest is getting the PPS for disciplining an oscillator.
Odetics doesn't recognize the model number 335-101-1 that was given on ebay,
it could be wrong. BTW the ebay number is 563393815 and it has a picture.
If anyone can point me to where I can get additional info I'd appreciate it.
thanks

Hello Witty

You may want to consider a frequency other than the 900Mhz area. Amateur radio interest in this band has increased as commercial radios are now plentyful since Nextel came to market. Many folks with part 15 900Mhz gear may find it unusable.

If you can find any 40's or 50's vintage ARRL Antenna or Handbooks, they dealt with 2x4 "A" frame supports. Not too common any more with Rohn and the like now being the stuff to use. But with the advent of pretreated lumber, wooden supports just might not be the "you've got to paint it regularly" hassle that they used to be. I seem to remember structures of about thirty feet or so being mentioned.

I've had one in my back yard for nearly 20 years now, just over 40 feet tall and made from Douglas fir 2 X 4's. I've painted it a few times with deck or siding stain, and it's still sound. The trick is to keep it off the ground, which I do by setting it on three concrete pyramids with bolts to keep it from falling off. I had another one up for quite a few years made from 2 X 3's which was much lighter and plenty sturdy. I took it down when my Seqoia got taller than it was.

I don't know what frequency you're talking about, but I've used them at HF
at the 100-watt power level, and at VHF at up to 50 watts without any
trouble.

The AMP company web page specifies their 50 ohm BNC connectors for a maximum working voltage of 500 volts RMS. With a 1:1 SWR it would take 5KW to develop that much voltage. The maximum current is not specified but it should be as good as any RG58 coax you are going to get to fit into the connector. You should be way on the safe side with 25 watts.

>

You'll find the ratings VERY conservative on good quality RG-8X.

I use RG-8X at 1500 watts all the time, and have never had a failure
ever.

I have some test cables that were made in the early 1980's, and they
are still working. They were used on a test bench checking new PA's.
Right now one set of those cables is between a 1500 watt 6 meter
amplifer and the power meter and from there to feedline. While they
get warm on CW at that frequency and power level, they haven't had
problems.

Hi Bob,

The DeMaw circuit does NOT work well, unless you are very lucky with noise to signal antenna phase.

That circuit does not shift phase more than a few degrees, except for a 180 degree flip as the level crosses zero. There is no mechanism in that circuit to rotate phase.

The internal portion of the BNC is the same as the N. While I have not used these levels, I would think legal limit at HF would be no problem.

Hi Bill,
The radio was designed to work off of 9volts; that means all the transistor's biassing was for 9volts. It might run off 12 volts, but may not work properly. Also, if the voltage rating of the electrolytic capacitors were only 10 volts, you would be stressing them. I would not take the chance. If you have measured your 12 volt supply and it really reads 12volts, not 13.8 or something else, then a quick and dirty voltage reduction scheme would put 5 rectifier diodes in series to drop 12 volts to a nominal 9 volts (nominal .6v drop for each diode)--use the common 1N4000 series diodes, rated for 1 amp. Or choose the number of diodes to drop whatever voltage your supply really puts out, to around 9 volts. 8.5-9.5volts should be OK.
And, of course, why not just run the radio with the 9volt battery it was designed for.

Excellent point Dale.
In fact, you have just motivated me to go downstairs to the basement and pull out some adapters. I am now holding a male N connector that mates perfectly with a female SMA connector. It doesn't lock of course, but it provides a great RF path. The coupling nut on an N connector is there for mechanical reasons, the RF path flows through the ring about the center conductor.
I saw this a few years ago, and I was amazed. Hopefully other NG readers will appreciate this also.

Source record: 54228

I found that my new transceiver picked up some strange noise. It was most prominent on 80 meters. The noise sounded like intermittent line related noise (60 hz buzzing). The spectrum display on the transceiver (Icom 756 pro) showed a band of spikes, with one spike about every 800 hz, and the group of spikes would occupy about 20 to 30 khz of band space, and the space it occupied would move around unpredictably. It was strong enough to make it hard to listen to all but the strongest signals. I tried turning things in the house off, one by one, until I finally traced it to my computer network. I have three computers, hooked together in a network hub, and one of the computers is at my ham station.

Well, I found that disconnecting the network cable from the computer at the ham station would usually stop the noise after a few seconds. I figured that the network was just sending messages back and forth all by itself to keep from getting bored. I tried putting numerous turns of the network cable through a big FT 271-61 toroid, and it had no effect at all, no matter where I put the core. Finally, I tried networking just the computer in the ham shack with one of the others using a crossover cable, and not using the network hub (which is required for more than two computers in a network). Bingo!- good network connection, no noise. So the network hub (a Linksys 5-port 10/100 mb/s hub, about a $40 item, if I remember right) was the source.

I figured maybe the hub was putting noise back on the power line, so I tried wrapping the wire from the plug-in transformer around a toroid before plugging it into the hub. This didn't help at all.

Finally, I noticed something strange- it was quite a large wall wart, but it was very light- there couldn't be a big transformer in there. Then I tumbled- it was a miserable little switching power supply. I sawed it open, and found that it had a circuit board, with a couple of little high frequency transformers, and a lot of components. Obviously, the toroid I tried in the line from the transformer to the hub was useless- the little devil was plugged right into the power lines.

I put it on the workbench and tried to arrange some toroids, common mode and differential mode, on the ac input, and nothing would keep the noise from getting into the power lines- I gave up, got a 6.3v filament transformer, bridge, filter cap, LM317 adjustable regulator and two resistors, and made a 3.3v dc regulated supply for the hub. It's now as quiet, rfi-wise, as you could want.

It was new to me that a wall transformer could contain a switching power supply. It was also interesting that during the tracing of the noise, the radio was operating on a car battery, so the noise wasn't getting in through its power leads. The power lines in the house were radiating the rf noise, and it was being picked up by my wire antenna, outside the house.

One other interesting thing was that the noise would disappear or at least shift frequency when I disconnected the network cable from one of the computers. I surmise the reason is that the switching power supply draws more from the lines, and injects more noise into them, when its load increases.

1533. Monitor noise

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-11 05:44:20 UTC
From: John O'Flaherty <oflahert@toast.net>
Message-ID: <3AAB10B4.61AF70CC@toast.net>
Source record: 54229

I notice that my computer monitor puts a lot of noise into my
receiver. It's especially noticeable when I'm tuned to some carrier,
which sounds buzzy and unclear, and then becomes clean when I turn the
monitor off. It improved things when I grounded the chassis of the
monitor with some tubular braid to the same point as the computer and
the radio, but it's still there to some degree.
It occurred to me that one of those LCD monitors might put out a lot
less noise, since there's no high voltage or current at high frequencies
for deflection. Since they're not cheap, I'd like to know first, has
anyone tried one of these, and is it actually better?

john

1534. AD9854 DDS

Newsgroup: rec.radio.amateur.homebrew

From: paolo@odone.it
Message-ID: <006501c0a9ff$7d467ce0$5f791c97@odone>
Source record: 54230

I am very interested on a low phase noise DDS, to be used as 1st LO on a single conversion homebrew transceiver, (9MHz IF).
Right now I am using a well known AD9850 clocking at 120MHz (noisy oscillator).
Is there any project using an AD9854 clocked at 300MHz (external clock)?
Thanks.

Source record: 54231

Ramsey did have a website at one time, but they are not very good at responding to e-mails... I have built some of their kits, and was less than pleased with the performance. For info, look at some of the Mod pages, they will sometimes have info which may help you in setting the freqs with the diodes. If this doesn't help, let me know, and I'll try to find somethinng for you. I still have the manual for the 440 version, and we may be able to "devise & develop" the freq settings for you with that info.

John O'Flaherty wrote:

> I notice that my computer monitor puts a lot of noise into my
> receiver.

Computer monitors can be a real nightmare. You can get interference
from the video signal, harmonics of the H and V sync, hash from
digital control circuitry and noise from the switching power supply.
If the monitor is very close the receiver, the magnetic field can
cause FM of the VCO circuit in a PLL rig.

If the signal is radiated directly from the monitor, there is very little
you can do about it. Moving the monitor further from the rig or
moving the receiving antenna further from the monitor will probably
help.

If the signal is radiated from the power or VGA cables, you should
be able to reduce it with a couple of large ferrite cores. This sounds
easy in theory but can be very difficult in practice.

A lot of monitors have an energy-saving feature that puts the monitor
into a low power mode when there are no sync-pulses from the
computer. Check your screen saver and BIOS settings to see
if you can put the monitor to sleep when you are not using the
computer. Changing the screen resolution won't get rid of the
QRM but it might move it to a different frequency. Computers
always work in accordance with Murphys law - if there is
only one harmonic within the entire band, it will always be
on the frequency that you want to use.

Good Luck.

1538. FS: Group of 5 Books on Transistors/Electronics

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-11 14:43:30 UTC
From: oldbooks78@aol.com
Message-ID: <20010311094330.26170.00000752@ng-ca1.aol.com>
Source record: 54234

I currently have for sale a group of 5 books on transistors/electronics, all in very good or better condition. The books are: (1) "Transistors: Principles and Applications" by R.G. Hibberd, published in 1965. The 304 page hardbound book is in fine condition, fresh and clean except for a Naval Research Lab property stamp on the title page and again inside the rear cover. (2) "A Dictionary of Electronic Terms" edited by Robert Beam, published in 1959 by Allied Radio. The softbound 80 page book is in very good condition, clean except for a previous owners name marked out inside the front cover. (3) "Understanding Transistors, Allied's Handbook of Transistor Fundamentals" by Milton Kiver, published in 1962 by Allied Radio. The 64 page softbound book is in fine condition, clean inside and out. (4) "Allied's Electrical Data Handbook" by Eugene Carrington, published by Allied Radio in 1956. The 64 page softbound book is in very good condition, clean except for a previous owners name marked out inside the front cover. (5) "The Practical Dictionary of Electricity and Electronics" by R.L. Oldfield, published in 1959 by the American Technical Society. The 216 page hardbound book is in fine condition, fresh and clean inside and out, in a very good dust jacket (some wear to the dust jacket edges). Available as a set for $8 plus $3 postage (book rate within the US, at cost elsewhere). If interested, please email to "Oldbooks78@aol.com" to reserve. Thanks, and best regards.

Take 3 noncunductive poles. Tie them hear the top, then lift them up
into a tripod (teepee supports). Just drop the line across the fork and
you're in business.

>Paul i1odp

The AD9854 is a much nicer part than the AD9850. There are more bits in the Phase accumulator, phase truncation path and DAC. You will be pleased with the part.

Analog Devices has a nice demo board, but (shameful plug here) my company makes a nice board (http://www.novatech-instr.com, see the DDS8m), but it will be too expensive for hobby work.

You have to choose your oscillator and PLL mult factory carefully to get good performance. Off-the-shelf dip oscillators are NO GOOD!!

Send some email and I can give some tips (without the sales pitch).

Have fun.

Hi John,

There's a glut of military surplus field masts on the market. They
come kitted up ready to deploy (no instructions provided) a 30 to 40
foot tall mast guyed at two or three levels. You get the mast as
stackable 5 foot tubes (heavy wall), guy plates, guy lines, stakes,
and sledge hammer for stakes (no instructions provided).

As a kit, not much bigger than my old seabag (same color, same
material). $90 and 40 footer was mine.

Hello there John ... Tom KI3R Port Vue Pa. I ran an inverted vee for a number of years on 40 using metal TV mast. Now I know some guys will say that the metal and its inherent length will cause difficulties. I had none. However I did turn down a dowel rod to fit inside the last section and used a HyGain balun there. Again if there were problems my signal or neighbors didn't let me know. Just be sure to guy obviously ..I used 2 at 90 degrees to the wires ... rayon line if I remember.

God Bless 73 Tom

G'day, as for the inverted "V" I have a B & W end fed wire antenna in a inverted "V" configuration and it works great the centre is about 50 feet high and both ends about 12 feet off the ground.

I work DX all over the world and have good coverage on 80 meters 300 to 600 miles at least running only 100 watts..

Ive noticed MANY CB'ers posting How to MODIFY & operate Ham equipment on the CB freq's [assuming its only cb they're wanting],that is how to get "general coverage TX".

It is ILLEGAL [in VK at least] to assist ANYONE with modifications to equipment for unlicensed/illegal usage,This is punishable by law via the ACA.
You'll notice the NG's are full of questions on HOW TO,They blatantly ask without ANY concern if you're caught helping them,and maybe afterwards even boast about how they PLASTERRED a ham.

In my opinion you first should ascertain their amateur callsign,THEN CHECK IT.

The world is full of apathy,statements like "what can i do to make any difference" ,WELL, you can simply by stop helping illegal activity.

The majority of hams are not involved here but there are a few who either want to show "how clever" they are or are just apathetical.
Ive got my "flack jacket"on because im gonna get roasted here but the short answer is stop helping illegal activities,there is no grey its either black or white.

Cheers people,Rod

HI. Josh DeWinter here again. Thanks for all the help from my last inquiry, everyone who responded. I've ordered the books that were recommended, and I'm looking forward to diving into them. (This is not a sudden urge for me, but a lifelong desire. I hope these can provide a lot more info. Its amazing how you can flounder around forever yourself, but when you ask someone who knows, how much quality information you can find).

OK. Enough of the last post. Here's my new scenario/question: I would like to build some kind of a VHF reciever project. It was recommended to me that I find and use one of those nifty FM reciever-on-a-chip IC's, as I don't know a ton about the individual stages of FM reciever construction on the component level yet. Can anyone recommend a good IC I can find to do this? The simpler the operation and external components, the better. I am looking to recieve right smack in the middle of the VHF business band, around 154 MHz.
Thanks for your help

I don't think Odetics is a GPS manaufaturer. I think they make broadcast station/studio equipment. So the GPS you have might be an OEM version of one of the more traditional manufaturers. Why don't you open it up and look at the boards and chipset?

Also, if when you power it up, you can measure the voltage on the antenna cable, you can match it with another antenna. Most have a preamplifier inside which requires an operating voltage.

At several hamfests I've seen something which looked just like a welding rod but was used (with a propane torch) to solder/weld aluminum.

On the home front, I've had some success soldering through a blob of pasty silver polish.

Source record: 54160

Paolo,

Be careful with the 9854 and high speed clocks. The standard part is only rated to 200 MHz. There is a second part that has a metal heat sink sticking out of the bottom of it. This part is rated for 300 MHz.

The 9854 is fairly quiet in terms of phase noise. However it has a lot of spurs coming out of it. I would highly recommend some kind of VCO locked to the 9854 if you are going to use it as a first LO.

Most people lock the VCO to the dds via a PLL chip. If you do it this way you may not have to clock the dds quite as fast.

Hope this helps.

Personally, I figure that most hams know how to read a schematic and modify a circuit, so I never respond to these type of questions on a public forum. In some cases, I'll verify the requesters' callsign and then reply to them via personal e-mail, but the key is to never post the info on a public forum, especially to an anonymous poster.

Body handling: HTML body converted to readable text

Paolo
I have nearly got the software written for such a board driven by a
AT90S8535 (Atmel AVR) micro
Currently I can tune the DDS using a rotary encoder and get a n output
accurate to 1 Hz. I am writing the software for the keypad a t
present.
At some point I will have to do a second version of the boards for
this project. The DDS board will have to be redone because of some
errors and I will have to use different regulators - the current ones
get too hot at max clock.
As the boards are DS PTH they are quite expensive with a minimum setup
cost of about AUS$400 - if there is sufficient interest I will
proceed.
I am using the plastic (non heatsink) version of the AD9854 - the
slug version needs a special multilayer board. I can run mine at
150MHz and the output looks and sounds quite clean with no processor
noise on the output as the DDS is tuned with the rotary encoder.
This may be adequate for your needs - it would give a usable output to
60 MHz or so

Hi,

Also make sure your monitor has a toroid on the wires going to the
neck of the CRT. If it doesn't buy a snap on one at Radio Sack and try
that.

The TDA-7000 by Phillips is a FM receiver on a chip.
It just barely works on the FM broadcast band without an
RF stage. Also, the schematics you will find are all
for broadband FM. There is a rare and impossible to find
"narrowband FM" applications note that explains how to use
the chip for narrowband FM.

Another simple design approach is super regen. It is very
difficult to made super regen work with narrowband FM,
but Charles Kitchin has done this. See his recent QEX article.

The easiest way is to use a 4:1 balun driven by a 1:1 choke.

I use a 9:1 bal-bal transformer (voltage-type) driving my 450 ohm
open-wire line, and a 1:1 choke balun to drive it because I have coax
feeding the trifilar winding of the 9:1 transformer.

This is a standard proceedure, and would work for you.

It should work OK though you'll probably have to realign the transceiver, most crystal-controlled sets aren't designed to cover a 20MHz band. (after you realign it, it will no longer work properly at 161.45MHz. If you're wanting to use the radio both in amateur and commercial service you're probably going to have to get a different radio.)

I do presume:

1. You have an amateur radio license. (without which you are not allowed to transmit in the 144MHz band. I don't know how likely you are to get in trouble for that in Singapore but in the USA there are serious fines.)

2. You don't actually plan to operate on exactly 144.0MHz.

Hi Al,

This all harks back to the designers of this series of connectors- Neils and Concilman (spelling?) Think they worked at Bell labs. Anyway, Neils named the N connector after himself while Concilman gave his initial to the C connectors. The BNC then is a Bayonette Neils-Concilman.

As a follow-up on this chip, see http://www.smartkit.gr/sk1055.htm
for some info on a WB FM rx using this chip. With some work on the detector,
and perhaps a narrow filter, it might be made to work a bit on NBFM.

BTW, I seem to recall that Motorola made a NBFM rx chip a few years back. A
search of their site might yield something. I *think* it was an MC 33660 or
something like that.

Good luck

You can do it directly with coax in theory, but I've never tried it in practice. You would need two coils that have minimal mutual coupling. You might be able to satisfy this requirement by putting the coils at right angles to each other and moving them as far apart as practical. At one end (the high Z end) connect them in series by connecting the braids together and using the center conductors for the balun connections, and at the other (the low Z end) connect them in parallel. You can use the coax lengths and number of turns in the ARRL Handbook for each coil. Tom's method might be better, but it would interesting to see if an all-coax one would work well enough. It would do best on about three adjacent bands. Beyond that, it's likely to add reactance to the system.

Do you want to convert it to 144 from 161? Is it a single channel unit?
If so, you could change the crystal and you would have to retune the
tuned circuits for 144. Shouldn't be a problem if you're comfortable
doing this. And...this is assuming there is enough range on the
variable coils or capacitors in the tuned circuits.

You may find "trimming" the antenna the wrong thing to do since you are lowering the frequency. You will need to extend it. Lower Freq.=longer wavelength=longer antenna.

I don't know why I missed that!

If we are thinking of the same thing, I have done something similar in
PA's. If I remember correctly, bandwidth is maximized when the line is
half of the output impedance when doing a 4:1 transformation. So he'd
be better off with 75 ohm lines or higher if he could manage.

The lines are choked, are in parallel at the input. They are in series
at the output.

Thanks Roy.

Using ferrite cores should help a lot. If you can't get a ring big enough,
look at http://www.geocities.com/wa2ise/radios/ham.htm for a trick
using ferrite bars instead.

Hi Dan,
Well, I have not worked with a 12-way splitter, but have used MCL's 2-way splitter/combiners a number of times at work. I haven't run specific IP tests on any of them, but can say they will generally tolerate up to about +20dBm for two tones input. Of course, a broadband feed to a 12-way splitter might not have a couple of very strong tones, but the total aggregate might add up to an average fairly high level. I would probably be more concerned with the preceding amp going into distortion, than the small passive transformer used in a splitter.

It might not hurt the radio, but you will probably get VERY low
output...you are trying to transmit on a frequency about 10% lower than
where it is tuned up. Receive sensitivity would probably suck as well.
The other problem is if the use a bandpass filter tuned to the 161 area,
you may not get nuch signal in to and out of the unit. As hams, that's
the beauty of it...we're allowed to try stuff like that :)

Still haven't read if you have an amateur license or not. Also be aware the
low end of 2M is reserved for weak signal work not FM.

John,

Thanks for the information. I have just begun a similar troubleshooting exercise here - also with a Linksys router. Mine is an 8 port Cable/DSL 10/100 router. I have observed that running at 100T is a LOT noisier than running at 10T, and I have intentionally routed my shack's UTP network feed through a secondary 10T hub to limit the speed of my shack PC to 10 MBPS. This really quiets things down, but there is still spurious noise across the bands (worse on 10 meters - my favorite band <sigh>, but still noticeable on 20 and 30).

My router does not have a "wall wart", but a line-cord mounted power supply. I had not considered replacing that supply with a stock DC supply, but will experiment with that to see if it solves the birdie problem.

Thanks again for your post.

Hi Jeff,

I realized an adapter for a very old spectrum analyzer using an ad-converter
and a simple pascal program. Just have a look, maybe you can modify it for
your purposes ?

It's a bit of a pain, but passing each output lead through the center of a
Fair-Rite #43 toroid twice before plugging it into the router will also quiet
things down. It doesn't seem to affect the performance at all. You might also
try the Steward 28B2029-0A0, which just clips onto the wire.

Doug Moore.

Philip,
I was going to suggest the following URL's, but you have to be a member of ARRL to be able to get them. Mouser (http://www.mouser.com/) is listed as a source for boards and kits, however searching their site was fruitless. The part numbers should be P/N 371-HFAMP1, -HFAMP2, and HFAMP3.

Good Luck!
Larry, W2GL

1603. Is QST Receiver Selectivity Article correct?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-13 17:53:05 UTC
From: Harvey Tetmeyer <k5ljm@mindspring.com>
Message-ID: <98lmpj$1t6$1@slb7.atl.mindspring.net>
Source record: 54103

I have been trying to understand Larry Scheff's (W4QEJ) receiver article in the February and March issues of QST. He somehow thinks that if he cuts back the RF gain enough, interfering signals magically disappear and nothing but the desired signals come on through.

I know that strong unwanted signals do blow right on though the broad, high gain front ends in the modern transceivers and create broadening of the signals somewhere along the line before the filters and detector. A little RF attenuation helps here but it does not change filter characteristics as Larry indicates.

He inverts the bandpass curve and calls it an attenuation curve. which it is. then draws the conclusion that any signal below the curve totally goes away, even if it is in the passband.

If I understand his writings, he infers that:

1. Bandwidth changes with amplitude. This would cause a lot of clipping.me thinks.
2. There is a threshold below which no signal gets through. He shows this in the shaded areas. This is possible with DSP but I don't think you'll see it in conventional mechanical or crystal filters.

Am I missing something or is this extensive two part article flawed?

Harvey, K5LJM

Actually its a 6-channel unit with 5 empty xtal sockets. I just want
to insert a 144.xxx xtal into one of the empty sockets and use it at
that freq occasionally. I don't plan to re-tune any of the circuits.
I presume then there will be a loss of range, but thats OK. Perhaps I
can limit that loss by tuning the antenna. I just don't want to damage
the set.

I don't plan to realign the circuit. There are actually 5 empty
crystal sockets on the PCB (the front panel selects any of 6 freqs). I
would leave the original 161 MHz xtal in the first socket and insert a
144.xxx MHz xtal in one of the spare sockets. All I want is to
ocassionally operate the set at 144.xxx so I can talk to my handheld.
Reasonable loss of range is OK, I just don't want to damage the
circuit in any way.

Thanks for the advice.

While it would be nice if it was cheaper, compared to most technical books, it is a bargain. The price listed in the latest issue of QST is $32 (plus $7 postage if you can't buy it locally). It would be hard to find many technical books that sell for less (except for the rest of the ARRL books). The only reason I could afford Rohde's book on receivers was by joining a book club, and that had it's problems.

I bought the 2001 ARRL Handbook a few months ago, and paid $51.36 Canadian, so the US price is downright cheap.

You don't need to buy the very latest edition. A new edition is published every year, but other than some construction articles, there is very little variation between editions. I seem to buy them every 7 years now.

So you can look for an older edition. The best place might be a fleamarket put on by a local ham radio club. People will sell off their older editions, and at a much lower cost. This is also a good place to find other technical books cheap, as well as components, test equipment and other electronic junk. You can find a list of upcoming hamfests at http://www.arrl.org

Although I've never found any myself, you might try used bookstores, especially one that deals in technical books. Even if you can't find a Handbook there, you might find other books that will be useful, at a more decent price.

I've had more success at used book sales. These are put on by libraries, Rotary Clubs, high schools, and groups associated with universities. Here, I haven't found recent editions of the Handbook, but I've found thirty year old editions for under a dollar. I also found my copy of The Radiotron Designer's Handbook for $3 a few years back at a sale put on by a group to raise money for university scholarships. And at the same sale, just last fall I picked up a number of books on cellphones and

"wireless communication" for a few dollars each. I had no need for these, and would not have spent fifty dollars or so for them, but for a few dollars, I had a chance to read up on new areas of technology. What you can find at these sales depends on what people donate, so it varies from sale to sale. I also imagine that some locals would be better than others, depending on local industry, etc.

Try contacting a local ham club, there's a list of at least some US clubs at the ARRL site. Many have newsletters which include a classified ad section, and you might find someone locally that has a used Handbook for sale.

Or try advertising in rec.radio.swap if you're open to buying by mail from an individual. Or EBay, for that matter.

It's fairly easy to find a used edition, since so many copies have been printed. It probably is harder to find used decent edition, since many will still be using theirs.

I thought the ARRL puts the previous edition on sale when the new edition is published. If this happens, it would be in the fall.

Many libraries have copies of the ARRL Handbook, so it's worth checking their. Not as handy as having your own copy, but it is cheaper.

Have an Oskerblock swr-200, but not really impressed by the accuracy. It is not much used, but would like to know what others might think of it. Perhaps just as good to remove the bridge and put some more modern powermeter bridge for better sensitivity on 1.8-30MHz. Have also Bird model 43 for more accurate readings.
Suggestions?

1613. Vintage VHF/UHF equipment

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-13 22:33:16 UTC
From: "Phil T. (VA3UX)" <phil@vaxxine.com>
Message-ID: <3AAEA02C.3230D20F@vaxxine.com>
Source record: 54111

have two pieces of what I would call "vintage" commercial radio
equipment.

One is a GE Transmitter/Receiver combination; all vacuum tube, power
amp
uses a 5894. Currently set-up for 168.99 Mhz. This is the original
cabinet which is about 3 feet tall, 2 feet wide and about 10" deep
(kinda
of like a big cereal box). The receiver and transmitter are on separate

chassis and can be removed from the cabinet. each has its own integral
power supply. Weighs 60 - 75 lbs (estimate)

The second is a Motorola repeater set-up for 412.0125 Mhz
transmit/417.0125
Mhz receive. This appears to be vintage solid state. Weight is around
80
lbs+ (estimate). Cabinet is similar size and shape to the GE unit
above.
Model number is XC34MSY-3IQ1CT.

These were both working when taken out of service last year. I bought
'em
but I really doubt I'll get around to using them (too many other
projects
on the go).

Any interested parties out there, please make reasonable offers. I'm
not a
VHF/UHF guy, so if these are just plain junk, feel free to tell me so.
There's a good pile of parts in these that I can use for something else.

Please reply direct to : phil@vaxxine.com

Thanks

Phil

Hi,
the "rare and impossible to find data sheet" (AN192) can be found here,
thanks to an indonesian guy who digitized it...

http://me.internet.co.id/orari/ic/tda7000/tda7000.html

There you will find how to use TDA7000 for reception of narrow band FM
signals: the trick is to use an external oscillator, so that the
internal frequency lock loop (used to compress the fm deviation of the
incoming signal) cannot work.
As a personal opinion, I am afraid that a narrow band receiver built
with the TDA700 will be affected by poor image reception, although
Philips claims this is not the case. However given the cost of the chip
(about 3 USD here in Italy), it could be worth a try.

I have not used them by myself, but as far as I know Motorola has
several receiver-on-a-chip available, like the mc3362 (discontinued
?!?), or the mc13135. Look here

http://ftp.qsl.net/ok2xdx/DK/rxminien.html

or here

http://www.sonic.net/~shageman/2_meter.html

for a circuit example.
